COLORS AND SHADES.—Not all light that falls on the surface of a subject is reflected. A brilliant white object reflects a high percentage of incident light, and a black object reflects very little of the light. Between these two extremes are the numerous tones of gray and colors of various hues and brightnesses. Each colored or gray object in a scene reflects a specific amount of light. A scene that consists primarily of light-colored or light-toned objects usually requires an exposure compensation to decrease the exposure as compared to the basic exposure for an average scene. A scene that consists primarily of dark-colored or dark-toned objects usually requires an exposure compensation to provide more exposure as compared to the basic exposure for an average scene. The primary reason light scenes and dark scenes require less exposure and more exposure, respectively, as compared to the average scene, is to maintain detail in the highlight of the light scenes and detail in the shadow areas of the dark scenes.

The color quality of a light source also has an effect on the amount of light reflected from an object; for example, a blue object does not reflect as much light when illuminated with a red light source, as compared to the same object being illuminated with a blue light source. This difference in reflectance is caused by the blue object absorbing the reddish light and reflecting the bluish light.

Any man-made light is an artificial light source. This light may be a tungsten lamp, a fluorescent lamp, a mercury-vapor lamp, and so on. The same factors that affect exposures for daylight apply to artificial light as well. Artificial light has some advantages. Distance, direction, and color temperature can be controlled using these light sources.

Bellows Extension

When copy cameras or view cameras are used, many subjects are photographed at very close distances. When you are photographing at these close distances, it is not uncommon for the bellows of these cameras to extend beyond one focal length. The farther the bellows are extended, the larger the image size produced at the film plane. When a 1:1 subject to image ratio (on the film plane) is needed, the bellows are extended to two times the focal length of the lens; for example, when a 6-inch lens is used to produce a 1:1 ratio, the bellows are extended to 12 inches. The distance the bellows are extended is determined by measuring the distance from the optical center of the lens to the film plane.

When the bellows are extended beyond one focal length, an exposure compensation is needed. Because light must travel a greater distance, some of the intensity is lost. This loss of light intensity must be compensated for by opening up the aperture or increasing the exposure time. There are two formulas used to adjust the exposure when the bellows are extended.

Generally, the exposure time is extended to compensate for bellows extension, because view cameras and copy cameras are mounted securely and the critical aperture is used to produce the sharpest image. To adjust the exposure time, use the following formula:

$$\left(\frac{BE^2}{FL} \right) \times T = \text{NEW EXPOSURE TIME}$$

Where: BE = Bellows extension

FL = Lens focal length

T = Indicated exposure time

EXAMPLE: You are photographing a document with a camera that has a 5-inch lens and the bellows are extended 7 inches. Your light meter indicated an exposure of 1/30 second at f/4. The new exposure time is determined as follows:

$$\left(\frac{7}{5}\right)^2 \times \frac{1}{30} = 1.96 \times \frac{1}{30} = \frac{1.96}{30} = \frac{1}{15} \text{ SECOND.}$$

To adjust the aperture, use the following formula:

$$\frac{\text{indicated } f/\text{stop} \times \text{focal length}}{\text{lens-to-film distance}} = \text{adjusted } f/\text{stop}$$

EXAMPLE: A 4-inch lens is extended to 4 inches beyond one focal length. The original camera settings are 5 seconds at f/11. Using the above formula, the problem is solved as follows:

$$\frac{11 \times 4}{8} = \frac{44}{8} = 5.55 \text{ or } f/5.6.$$

f/16 RULE

You should use a light meter for most of the photographs that you take in the field. These light meters are either built into the camera or are separate hand-held models; however, there may be times when your light meter does not operate properly, or you do not have time to use it in order to “grab” an awesome shot. The f/16 rule of exposure allows you to determine basic camera exposure settings for both black-and-white and color photography without the aid of electronic devices.

The f/16 rule states: The basic exposure for an average subject in bright frontal sunlight is

$$f/16 \text{ at: } \frac{1}{\text{film speed}}$$

Therefore, to calculate the BASIC exposure for bright, sunny conditions, set f/16 on the camera lens and use the ISO speed of the film for the shutter speed; for example, when you use ISO 125 film, set the shutter speed at 1/125 second and the lens aperture at f/16. For ISO 64 film, set the shutter speed at 1/60 second and the lens aperture at f/16, and so on. When the camera does not have a shutter speed corresponding to the ISO of the film, use the shutter speed that is closest to the ISO of the film.

The f/16 rule is based on the correct exposure for an average subject under bright, sunny conditions. If the sun goes behind a cloud, however, then the lighting on the subject is decreased and you must change the basic

exposure. The aperture settings for different daylight intensities are as follows:

- Bright sun on light sand or snow-f/22
- Bright sun-f/16
- Cloudy bright-f/11
- Cloudy-f/8
- Heavy overcast or open shade-f/5.6

For each of these different daylight intensity situations, you begin with the ISO speed to determine the shutter speed, set the aperture to f/16, and open up or stop down the aperture for the lighting conditions.

After calculating the exposure, you can change the setting to any equivalent exposure; for example, if you determine the required exposure to be 1/500 second at f/5.6 but you wish to use a small aperture for greater depth of field, you can change the setting to 1/60 second at f/16.

Remember, the f/16 rule provides you with a basic exposure for front-lighted subjects only. When the subjects are side-lighted or back-lighted, you must double or quadruple the exposure, respectively.

Because many cameras are fully automatic, you may wonder why you need to know basic exposure. There are three good reasons for knowing and understanding the basic principles of exposure. First, you want to control the depth of field and stop action instead of the camera controlling it. Second, a light meter cannot think. All a light meter does is respond to the light it receives. You must know when to override the camera; for example, when the subject is side-lighted or back-lighted. Third, meters are mechanical and can fail. They can be inconsistent, consistently wrong, or fail altogether. When you can work out in your head, roughly what the camera exposures should be, you will know when the camera or light meter is wrong. Knowing when a light meter is giving incorrect readings could make the difference between success or failure of an important photographic assignment.

LIGHT METERS

The correct use of a light meter greatly increases the accuracy in determining your camera exposure. You should also understand that the incorrect use of a light meter can result in consistently unacceptable results. To assure consistently acceptable exposures, you must become thoroughly proficient with the correct operation of a light meter.

PHC Ronald W. Bayles
302.91

Figure 4-19.—Hand-held light meter.

A light meter can be either built into the camera or a separate hand-held unit (fig. 4-19). Both types are sensitive instruments and should be handled with care. There is little maintenance, but they do require batteries. When you think a light meter is not working properly, have it checked by a qualified technician. Always be sure to check your equipment before leaving on an assignment. Like all camera equipment, careless handling and excessive heat and moisture limit the life of a light meter. A light meter must not be subjected to high temperatures for prolonged periods of time. Unless the light meter is designed for underwater photography, it should be protected in inclement weather.

LIGHT METER READINGS

There are two methods of measuring light with hand-held light meters. These two methods are the incident-light method and the reflected-light method.

Incident-Light Method

This method requires the use of an incident-light meter. An incident-light meter has a diffusing dome that covers the photoelectric cell. When an incident-light meter reading is taken, the meter is held at the position of the subject with the photoelectric cell pointed toward the camera. The meter measures the light falling upon the scene. The incident-light method of measuring light is used extensively in motion-media photography and gives fast accurate results in all photography.

Most light meters are designed for use as either incident-light or reflected-light meters. By removing the diffusion dome from the photoelectric cell, you can use the meter to measure reflected light.

Reflected-Light Method

When you are taking this type of light-meter reading, the diffusing dome should be removed from the photoelectric cell and the meter pointed toward the subject.

A reflected-light meter receives and measures the light reflected from a scene within the angle of acceptance of the meter. The term *angle of acceptance* compares to the term *angle of view* of a lens. Both are predetermined during manufacturing. The angle of acceptance and the distance between the meter and the scene are the controlling factors as to how much of the reflected light from the scene is measured by the meter. When the angle of acceptance is greater than the angle of view of a lens (when using a telephoto lens for example), the meter should be moved closer to the scene.

Light meters that are built into the camera are reflected-light meters. When these meters are used, the angle of acceptance is not greater than the angle of view of the lens being used. The meter measures the light from the scene as seen by the lens.

Some reflected-light meters have angles of acceptance between 1 and 4 degrees. These meters can be used from a distance to measure the reflected light from specific objects within a scene. Exposure meters with angles of reflectance this small are called **spot meters**.

LIGHT METER OPERATION

You must understand the way light meters operate to determine whether the information they provide is accurate. No matter what type of light meter you use, it

is an electrical-mechanical device that can only provide information for which it is designed. You are responsible for translating this information into useful exposure data.

Light meters are calibrated to see one shade only—middle gray. This means the information that the meter provides, no matter how much light is falling on the subject or what the reflection characteristics are, reads the subject the same as though it were middle or neutral gray (18-percent gray). Theoretically, if you take a reflected-exposure meter reading from an 18-percent gray card and expose your film according to the reading, the result should be a picture that matches the tone of the gray card exactly; however, when you take a light meter reading of a white or black object, the light meter still reads the objects as though they were 18-percent gray.

When you take a photograph that includes a gray, white, and black card, you will see how, depending on where you take the light meter readings, they affect your photograph; for example, when you take the light meter reading from the black card, the final picture reproduces the black as middle gray, and the gray and white cards as white. When you take the reflected-light meter reading from the white card, just the opposite occurs. In your final picture, the white card reproduces as middle gray, and the gray and black cards reproduce as black.

This example demonstrates overexposure and underexposure. When the reading was taken from the black card, the meter raised the black tone to middle gray, and the gray card tone was also raised so it reproduced as white. Thus both the black and gray cards were overexposed. The opposite occurred when the exposure was based on the reading from the white card. The white tone was lowered to middle gray and the gray card tone to black, resulting from underexposure. Only a light meter reading taken from the gray card allows all three cards to be imaged at their true tone.

A more practical example on the way a light meter reads 18-percent gray is illustrated in the following example. Suppose you are going to photograph a ship alongside a pier. Bright sunlight is striking the ship from the side, causing part of the ship to be in shadow. This creates a brightness difference between the highlight area and the shadow area. Both highlight and shadow areas are equal in size and importance. When you get close to the ship and take a reflected meter reading of the highlight area alone, you expect the finished photograph, like the white card in the above example, to be middle gray. When you stop down the aperture to the recommended exposure of the meter, you are also

reducing the amount of exposure from the shadow area. This results in a loss of detail in the shadow area of the ship, because it is underexposed. The opposite effect occurs when you take a meter reading from the shadow area. In this case, the shadow tones are raised to middle gray and have detail, but the highlights are overexposed and completely “washed out.”

If, however, there was an area in this scene whose tone was midway between the highlight and shadow areas, you could use it to take your light meter reading (like the gray card was used in the previous example). In this example, assume there is no tone midway between the two extremes. You can still get an accurate light meter reading of the entire ship. Since the highlight and shadow areas are of equal size, the *average* light meter reading you get will represent a tone that is midway between the two extremes.

REFLECTED LIGHT METER READING VARIATIONS

There are variations of light meter readings used to provide accurate light meter readings of different types of scenes. These methods are as follows: the integrated, or average, method, the brightness range method, the darkest object method, the brightest object method, the substitution method, and the bracketing method.

Integrated, or Average, Method

The technique of making reflected-light meter readings from the camera position is called the *integrated*, or *average*, method. This method was used and explained in the examples above. This method is accurate for the majority of photographs taken.

The integrated, or average, method of measuring reflected light is acceptable for scenes that consist of approximately equal portions of light and dark areas; however, when a scene is composed of either predominately light or dark areas, the meter reading may not be accurate.

The reason for these inaccurate meter readings can be more easily understood by using an example of photographing a checkerboard with alternating black-and-white squares. When the meter is held at a distance to include the entire board, the reflected light from both the black and the white squares influence the meter, so an average reading results. The light measured from this position is the integrated sum of both the white and the black squares, as though the checkerboard were one gray tone. The light meter reading from this point should produce an acceptable image.

If you hold the meter so close to one of the white squares that the black squares have no effect on the meter reading, the reading is higher than the integrated reading and the meter indicates that the scene requires less exposure. The same principle applies when a reading is taken close to a black square. The reading indicates that the scene requires more exposure. Each of the meter readings is a measurement of 18-percent gray. You can apply this checkerboard example when you photograph scenes that are predominately light or dark. Compensation is required to expose such scenes correctly.

As a general guide, you should double the indicated exposure when the light measurement is taken from a predominately light scene and detail is desired in the shadows. When you take a light meter reading from a predominately dark scene and detail is desired in the highlight areas, you should reduce the exposure by one half.

Brightness Range Method

This method requires you to take two readings from the scene: one from the highlight area where detail is desired and another from the shadow area where detail is desired. You then base your exposure on a point midway between the two readings.

The brightness range method of determining exposures for most scenes usually provides detail in both the highlight and the shadow areas. An exception to this is when the exposure latitude of a film is not capable of recording the brightness range of the scene. This can occur with scenes that have extremely great brightness ranges. A scene brightness range is the difference between the brightest and the darkest areas of a scene and is usually expressed as a ratio. The average brightness range of a normal scene is 160:1. Films used for pictorial work are capable of reproducing this brightness range. When the scene exceeds a brightness range of 160:1, you must compromise the exposure. This compromise can be as follows:

- Underexpose and sacrifice shadow detail to retain highlight detail.
- Overexpose and sacrifice highlight detail to retain shadow detail.
- Do not compensate and expose for the midtones and sacrifice both highlight detail and shadow detail.

Darkest Object Method

The darkest object method of determining exposures is actually a variation of the brightness range method. When you desire detail in the shadow area or darkest object within the scene, you take the light meter reading from this area. This method actually overexposes the film overall, causing the highlight areas of the scene to be greatly overexposed. This overexposure occurs because the light meter averages the light reflected from the shadow area and indicates an exposure to produce middle gray. When a great amount of detail is not needed in the shadow area and you want to expose the overall scene normally, you can take your light meter reading from the darkest object or shadow area and stop down two f/stops. This method provides a good overall film exposure of the shadows, midtones, and highlights.

Brightest Object Method

Another variation of the brightness range method is the brightest object method. The brightest object method of calculating exposures is used when a highlight area within a scene is the only area within the scene from which you can take a light meter reading. This method can also be used when you want to record detail in the highlight area. In both situations, you take only one light meter reading of an important highlight area. When you do not want the highlight to record as a middle-gray tone and desire a good overall exposure of the scene, you simply open up two or three f/stops from the indicated exposure. When you need maximum detail in the highlight area, you can use the reading that the light meter provides. This records the highlight area as medium gray. This method underexposes the film in other areas of the scene that reflect less light.

Substitution Method

With the substitution method, you replace an object within the scene with an object, such as a gray card. You then take a reflected-light meter reading from this object. You use this method when the other methods of determining exposure are not possible. Such situations may be caused by excessive distance between the light meter and the scene, barriers in front of the scene, or the size of the scene makes it impossible to get an accurate light meter reading. The substitution method is often used in studio situations where objects may be too small to obtain an accurate light meter reading.

You should select substitution objects that match the light reflectance quality of the object in the scene; for

example, a white card can be used to substitute highlight areas of a distant scene. A dark or a black card can be used to substitute a shadow area, an 18-percent gray card can be used to represent middle gray, or the back of palm of your hand can be used to substitute a gray tone.

When the substitution method is used, take the light meter reading from the substituted item under similar lighting conditions that exist in the scene. When the scene is in bright sunlight, the substituted object must also be in bright sunlight. Likewise, a scene in shade requires a substitute light meter reading in shade.

You can use each of the methods discussed previously with the substitution method. An 18-percent gray card can be used for the integrated or averaging methods, a dark and a light card can be used for the scene brightness range method, a dark card for the darkest object method, and a light card for the brightest object method.

Bracketing Method

There are times when unusual lighting or subject brightness prevents you from getting an accurate light meter reading. In these cases, a good insurance policy is to bracket your exposure. To bracket, you should take one picture at the exposure indicated by the light meter, and then take two more exposures: one at one f/stop under the indicated exposure and another at one f/stop over the indicated exposure.

When you are in doubt about the correct exposure for a negative type of film, it is always better to overexpose than underexpose. Even though overexposure produces excess densities in the negative, it still provides a useable image that can normally be corrected in the printing stage. When underexposed, if the image does not exist on the film, no corrective printing techniques can provide image detail.

When shooting reversal film (slides), you should bracket in 1/2 f/stop intervals. Because the exposure latitude of slide film is limited to $\pm 1/2$ f/stop, you should bracket in 1/2 f/stop increments, both under and over the indicated light meter exposure reading. Color slides that are 1/2 f/stop underexposed have more color saturation and are more usable than ones that are 1/2 f/stop overexposed and appear “washed out” and light.

TAKING LIGHT METER READINGS

When taking light meter readings, you must be sure the reflected light that influences your light meter is actually from the object you want to photograph. Stray

light, backlighting, large dark areas, and shadows can all cause erroneous light meter readings. When using a light meter, be sure that shadows are not cast from the light meter, camera, or yourself. When a hand-held light meter is used, the distance of the light meter to the subject should not exceed the shortest dimension of the object; for example, when taking a light meter reading of a person’s face that is approximately 9x6 inches, you should hold your light meter about 6 inches from the face of your subject when taking the meter reading. When using a light meter that is built into a camera, be sure to focus on the image before taking a light meter reading.

CAUSES OF FALSE LIGHT METER READINGS

There are a number of reasons why light meters give erroneous or bad readings that produce underexposed images. You can prevent these bad readings by being aware of the conditions that cause them.

Light Entering the Viewfinder

Light entering the viewfinder and falling on the viewing screen can cause underexposure. Most TTL meters read the light falling on the viewing screen from the lens. When strong lighting is coming from behind the camera, it can influence the light meter. When an occasional underexposed frame in an otherwise successful series occurs, the cause may be light entering the SLR viewfinder. Make a point of shielding the viewfinder if you do not have a rubber eyecup. When you use a tripod, have the camera set on automatic and cap the viewfinder to prevent exposure errors.

Incorrect Film Speed Setting

When the majority of frames on a length of film are consistently underexposed or overexposed, the most likely cause is you have the wrong ISO set on the film speed dial. For black-and-white film and color reversal film, it may be possible to compensate for this in developing if detected before the film is processed.

Bright Subject

A bright object or highlight area can affect the sensing area of a spot or center-weighted TTL meter. This results in an underexposed image. To prevent this from occurring, you should ensure the sensor is pointed directly at a midtone within the scene, and use this as the camera exposure. When you frame and compose

Figure 4-20.—4x5 Graphic View II camera.

237.192

your image, the light meter may indicate a different setting. Be sure to leave your camera set at the indicated midtone setting. Normally, light meters that take integrated or averaged readings of the field of view cannot be fooled in this instance. But remember, even integrated systems cannot cope with extremely bright areas that take up a significant portion of the frame.

Bright Background, Dark Subject

When you are taking photographs that are back-lighted or against a light background, there is always the danger of underexposing the main subject (unless you use special techniques to fill in shadows, such as using a reflector or a flash unit). Be careful to take a reading from only the shadow side of the subject in these situations.

Too Little Light

The most frequent cause of underexposure is trying to take pictures when there is not enough light. Light meter readings are not very accurate at these low-light levels. When you want to make photographs under these conditions, be sure to use a tripod and bracket to provide more exposure than indicated by the light meter. You also can switch to a higher ISO film. Some of the high-speed films marketed today can provide remarkable results.

There are several other causes that may cause your images to be exposed incorrectly. Some of the most common causes are listed as follows:

- Wrong camera settings are set when transferring information from a hand-held light meter to the

camera. This can also occur when you attempt to override an automatic camera.

- Using a camera with TTL metering and placing a color filter with a high-filter factor over the lens.
- Wrong aperture setting when flash is used.
- Shutter speed is not synchronized with camera flash.
- Aperture or shutter speed setting is knocked while carrying the camera. Always check the camera setting before taking a photograph.
- Weak or incorrect battery in the light meter.

VIEW CAMERA

The view camera (fig. 4-20) is a flexible and useful camera that, due to laziness, is frequently overlooked by Navy imaging personnel. Through the use of rising or falling fronts, swings, tilts, and shifts, you have complete control over the composition of the subject. View cameras are excellent for photographing construction, large groups of people, landscapes, small parts, damaged material, buildings, and many other subjects, because distortion can be controlled or corrected. The camera has bellows that may be extended to make it suitable for copy work and photographing small objects. Most view cameras used in the Navy use 4x5 sheet film. View cameras are not suitable for sports or uncontrolled action situations where a hand-held camera is needed.

View cameras do not have viewfinders or range finders. Viewing and focusing is done on ground glass. The ground glass is located exactly the same distance from the lens as the film; therefore, the image viewed on the ground glass is the same that is recorded on the film. View cameras have interchangeable lenses and between-the-lens leaf shutters.

BASIC CONTROLS AND FUNCTIONS

All view cameras are basically the same. Generally, all view cameras have the following standard parts:

- Monorail or bed. Serves as the base or support to hold all the other components.
- Front lens standard. Permits the lens to be locked into any position on the monorail. The front lens standard also permits the lens to swing, slide, tilt, rise, and fall.
- Rear standard. The rear standard holds the film holder and has swing, tilt, and slide controls.

Figure 4-21—Swing movement of front and rear standards.

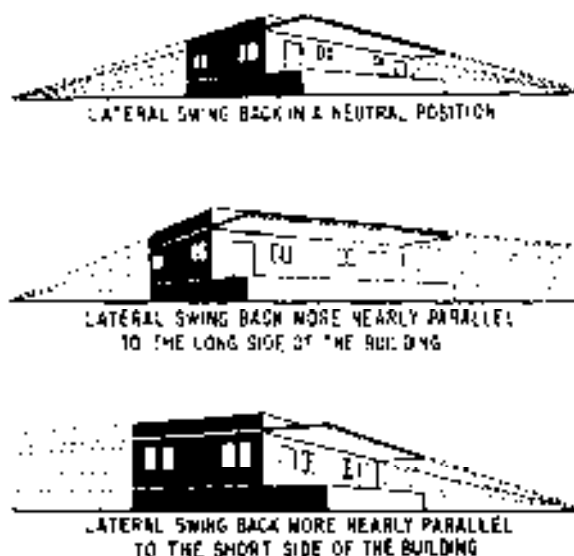

Figure 4-22.—Correction for horizontal distortion.

- Bellows. Connects the front and rear standards and allows the two standards to move for focusing or to accommodate various focal-length lenses.
- Tripod head. Holds the monorail to the tripod.
- Lens.
- Ground glass. Used for focusing, viewing, and composing the image.

There are four basic movements or adjustments used on a view camera. These basic movements perform specific functions. The four basic movements are as follows:

1. **Horizontal or lateral swing.** Both the front and rear standards swing horizontally (fig. 4-21).

The swing back is used to correct distortion, or perspective, in the horizontal plane. When you are photographing subjects from an angle, horizontal lines appear to converge at the distant side. To correct this distortion, swing the camera back so it is more parallel to the horizontal plane of the subject (fig. 4-22).

Figure 4-23.—Front and rear vertical tilt movement.

The front standard swing allows the lens to pivot horizontally around its optical axis. The swing front is used to increase the depth of field. When the swing back is swung, the film is not parallel with the image produced by the lens. By swinging the lens, you can bring the image onto the same plane as the film.

2. Vertical tilt. Both the front and rear standards tilt vertically (fig. 4-23).

The tilt back is used to correct distortion, or perspective, in the vertical plane. When you angle the camera up to photograph a subject, such as a building, the vertical lines on the ground glass appear to converge. When this distortion is not corrected, the subject appears smaller at the top and the vertical planes bend toward the center of the image (fig. 4-24, view A). To correct this distortion, tilt the tilt back so it is parallel to the vertical plane of the subject (fig. 4-24, view B).

The tilt front is used to focus and increase the depth of field. When the tilt back is tilted to correct for vertical distortion, the film plane is no longer parallel to the image produced by the lens. By tilting the front standard, you can bring the image of the lens onto the same plane as the film.

Figure 4-24.—Uncorrected and corrected vertical distortion.

Figure 4-25.—Sliding front and rear of view camera.

Figure 4-26.—Using sliding controls to center image.

Figure 4-27.—Using rising and falling front-to-center image vertically.

3. Slide or shift. Both the front and rear standard shift or slide from side to side (fig. 4-25).

The sliding front or sliding rear is used to center the image on the ground glass horizontally (fig. 4-26). The sliding front or sliding rear is used when the image is not centered after the camera is set on a tripod. These controls are used instead of moving the tripod. When the tripod is moved, the horizontal corrections are altered and must be reevaluated.

4. Rising and falling front. The rising and falling front is used to center the image vertically on the ground glass (fig. 4-27). This control raises and lowers the lens board. This prevents you from tilting the entire camera and nullifying the distortion corrections made on the vertical plane.

VIEW CAMERA OPERATION

The view camera is easy to use, but this requires some thought and patience to use it properly. The more

the camera is used, the more comfortable you will be with it. The following progressive steps are used when using the view camera:

1. Set up and level your tripod.
2. Set the camera controls to the neutral position. The neutral position is the starting point for photographs taken with a view camera. In the neutral position, all controls are lined up and no corrective movements are set. Adjust the front and the rear standards so they can be moved to focus the image.
3. Open the shutter and set the diaphragm at maximum aperture.
4. Roughly compose the image on the ground glass.
5. Focus the image.
6. Check the image size and subject coverage. When required, change lens focal length, camera-to-subject distance, or both. Small image size adjustments may be made by sliding the monorail forward or backward.
7. Correct distortion by using the swing and tilt controls. The image must be refocused after each control is moved.
8. Recenter the image horizontally by using the sliding front or the sliding rear. The image is recentered vertically by using the rising and falling front.
9. Refocus the image. To obtain greater depth of field, swing or tilt the lens board so it is parallel with the film plane.
10. Refocus.
11. Determine your exposure. When necessary, be sure to take the bellows extension into account.
12. Stop down the diaphragm and check the depth of field.
13. Check the circle of illumination. You will lose the circle of illumination when extreme camera

Figure 4-28.—How the loss of the circle of illumination appears on the ground glass.

302.139

movements are made. This is caused when the lens field of coverage is shifted from the film plane (fig. 4-28).

14. Be sure all camera adjustments are locked down and insert the film holder. Be sure the lens is closed before removing the dark slide.

15. Make your exposure.

You cannot always correct 100 percent of the distortion. Horizontal or vertical distortion can only be corrected on one plane; for example, when you take a three-quarter photograph of a building, only the front or side can be corrected at a time, not both in the same picture.

ELECTRONIC CAMERAS

Still-electronic cameras are becoming popular in all branches of the Department of Defense. The operation of still-electronic cameras is basically the same as conventional cameras. The only difference between these cameras is the way the images are recorded and stored. There are two different types of electronic cameras used currently in the Navy: the still-video camera and the digital camera.

The Sony ProMavica MVC-5000 (Magnetic Video Camera) is an example of a still-video camera. The ProMavica records images as magnetic impulses on a compact 2-inch still-video floppy disk. The images are captured on the disk by using two-CCD (charge-coupled device) chips. One chip stores luminance information, and the other separately records

Figure 4-30.—Comparing the angle of view of a 35mm camera and the Kodak DCS Digital camera.

the chrominance information. This camera provides a 720,000 pixel image.

The images can be stored on the floppy disk either as a **FRAME** or a **FIELD**. When *frame* is selected, each picture is recorded on two tracks and up to 25 images can be recorded on each disk. When *field* is selected, each picture is recorded on only one track, allowing up to 50 images to be recorded. When you record your pictures in the field mode, images are less detailed as compared to images recorded on two tracks (frame).

Overtaking the still-video camera is the digital camera. The Eastman Kodak Company is leading the way in digital-imaging technology by introducing the Digital Camera System (DCS). Resolution with the Kodak DCS 200 Digital camera is 1.54 million pixels,

PHAN(AC) April Hatton
302.271

Figure 4-31.—Image captured and transmitted using the Kodak DCS Digital camera.

providing four times the resolution of a still-video camera. Kodak's fully digital systems use a Nikon body and optics to capture the image. The image is then transferred to a highly sensitive CCD that converts the image directly into digital information. The CCD in the Kodak DCS camera system only uses a small portion of the angle of view compared to conventional cameras; for example, a 28mm lens on the Kodak DCS Digital Camera is equivalent to an 80mm lens on a 35mm camera (fig. 4-30).

The exposure index (EI) of the DCS camera equates to 50 to 400 ISO for color images and 100 to 800 ISO for black-and-white images. The digital images stored on the DCS camera can easily be downloaded to a computer, so it can be manipulated and printed or can be transmitted around the world without loss in quality. The image in figure 4-31 was transmitted directly from the USS *Ranger* CV-61 via satellite to the Navy News Photo Division in the Pentagon.

CHAPTER 5

BASIC PHOTOGRAPHIC TECHNIQUES

Today, photography is characterized by a rapid growth in the development of technology and ideas. Each year, millions of pictures are taken and an astonishing array of new films, cameras and imaging systems enter the market.

One of the great attractions of the photography field is the ease with which basic skills can be learned. Unlike some of the older arts that take years of training to produce an acceptable product, anyone can quickly learn how to take a picture; however, photographic techniques must be mastered before you can become an accomplished photographer; therefore, mastery of the basic fundamentals is the foundation upon which you will build your photographic and professional skills as a Navy Photographer's Mate. The photographic techniques presented in this chapter are essential in producing quality photographs, and you can apply each of these fundamentals, to some extent, each time you take a picture.

KEEPING THE CAMERA STEADY

Many photographs have been ruined because of camera movement. Unless you want a blurred picture, keeping your camera steady when shooting is crucial. The longer the exposure or focal-length lens you use, the more crucial holding your camera steady becomes; therefore, there are many instances when the use of a tripod or some other type of camera support is necessary.

The following section provides general guidelines for the various methods used to support a camera to ensure quality results. These are not necessarily the only or even the best ways to support a camera. You should practice supporting your camera using various methods; then select those that are most appropriate for the situation and the subject being photographed. Practice should include all the camera functions you normally use on actual photographic assignments. Concentrate on composing through the viewfinder, focusing, selecting shutter speeds and f/stops, holding

the flash off the camera, depressing the shutter release, and winding the film.

HANDHOLDING THE CAMERA

Of the various methods to keep your camera steady, the best is to use a tripod, but often you may not have one with you or the situation makes the use of a tripod impossible. In these situations, if you use proper precautions, it is possible to take high-quality pictures using hand-held methods.

Under normal circumstances, you should not handhold your camera at shutter speeds longer than about 1/60 second. When a long lens is used, this becomes even more critical, because the images produced by long lenses are affected more by camera movement. Also, it is more difficult to control the weight and greater size of a long lens when it is hand-held. As a general rule, the slowest recommended shutter speed is the reciprocal of the focal length of the lens; for example, when you are using a 500mm lens, the slowest shutter speed you should use is 1/500 second. When handholding your camera, be sure to have a good, solid, but not tense grip on the camera. Use your whole body as a firm support. Your elbows should be close to your body and your feet spread apart to provide good balance. In this position your body is acting as a tripod. When possible, you should try steadying yourself by leaning against something solid like a wall, tree, or post.

When using an eye-level camera, press the camera against your forehead and face. A waist-level camera should be pulled solidly against your body. Just before releasing the shutter, take a deep breath, let out part of the air-hold the rest, and squeeze the shutter release as if firing a gun.

When nothing is available to support your camera other than yourself, try sitting down, squatting, or kneeling, and firmly rest your elbows on one or both knees. When you are taking low-angle photographs, lying on the ground with the camera in front of you is another simple way to keep the camera reasonably

Figure 5-1.—Handholding the camera.

steady. Even better results are obtained when you place the camera on a solid surface, such as a railing or a rock (fig.5-1).

When taking high-angle photographs with a twin-lens reflex or waist-level camera, you could hold

the camera steady upside down against a roof or other object within easy reach above your head, such as under a low archway or firm tree branch.

Portable and compact supports, such as pistol or rifle grips, are available for hand-held cameras. These

are particularly useful when covering fast events, when using long-focal-length lenses, or when a tripod is too cumbersome to use. These hand-held supports are usually fitted with a cable release for firing the shutter.

Camera shake can cause *fuzzy* photographs. Some cameras have built-in capabilities that help reduce camera vibration or shake; for instance, on a single-lens reflex (SLR) camera, the mirror “jumps” up when the shutter is fired—that causes vibration. On some SLRs you can lock the mirror up before taking the picture to avoid this; however, the disadvantage of locking the mirror is that you are unable to see through the viewfinder. Also, the pressure of your finger on the shutter release can cause some camera shake. “This does not happen on cameras with a delayed shutter release because the camera compensates by automatically delaying the shutter release. Additionally, cable release can be used to fire the shutter without handling the camera

CAMERA SUPPORTS

To ensure absolutely sharp photographs, you must use some type of camera support. Few photographers can hold a camera absolutely steady, especially for exposures longer than about 1/60 second or even shorter exposures when using long-focal-length lenses. When using telephoto lenses or shooting motion media, you must remember that camera movement can become critical. Even the slightest camera movement is magnified and becomes very apparent in enlargements of still photographs or when motion-media footage is viewed.

The ideal camera support should be strong, firm, and allow as much adjustment of camera height and angle as possible. The design of a support to be carried outside the lab should be compact and lightweight, while still providing a firm, rigid camera support.

Most pictures are taken holding the camera by hand because camera supports are often bulky, heavy, and inconvenient to carry on many assignments; however, you should use a camera support when it is appropriate to do so. This allows you to produce the sharp pictures that are characteristic of a truly professional photographer.

Tripods

The best way to support your camera is with a sturdy, rigid, tripod. Tripods are three-legged camera supports with flat platforms or heads in which cameras are secured. Most tripods are equipped with a head that

has an elevator center post. The camera is attached to this center post and is raised or lowered easily by cranking the post up or down. These elevators eliminate the need for readjusting all three tripod legs for making small, last minute adjustments to the camera height.

Tripods come in a variety of designs, sizes, and weights (fig. 5-2). The heavier models are the sturdiest and provide the best support; however, if too heavy, they are not very portable. As a general rule, the heavier your camera, the heavier and stronger your tripod must be. For some of the light, full-size tripods, rigidity can be improved by hanging a bag of sand or another weight from the tripod head. This is especially useful in high winds. Another method is to hang a strap from the tripod head, and use the strap as a foothold on which to apply downward pressure (fig. 5-3).

Tabletop tripods are also available and can be used almost anywhere a flat surface is available. These small tabletop tripods can even be braced against the photographer’s chest. Because of their small size, they can easily be carried in a camera bag.

To set up a tripod, extend one leg straight ahead toward the subject. This way the camera may be aimed by pivoting the tripod on this one leg. Extend the other two legs and adjust them to level the tripod platform horizontally. When setting up a tripod on level ground, you can waste a lot of time trying to get the tripod level if the leg sections are not fully extended. An easy solution to the problem is to mark the tripod legs in specific increments with a marking pen, pencil, or scribe. One method is to mark short lines at 1-inch intervals and long lines at 6-inch intervals. Doing this reduces your frustration, saves time, and allows you to level your camera on the tripod with less effort. When a tripod is set up on an uneven surface, several adjustments of the side legs are normally necessary. Readjustment of the front leg levels the camera vertically so the platform or head is level. Most newer tripods have platforms that can be adjusted by eliminating the need for minor leg adjustments.

To mount the camera on the tripod head, you secure it in place by tightening the tripod screw into the camera tripod socket. Secure the camera by tightening the camera clamp screw locknut. After the camera is mounted on the tripod, test the camera to ensure all camera controls are accessible and function properly. The camera should be stable and not shake when the camera controls are operated.

Figure 5-2.—Tripods.

Figure 5-3.—Using a foot strap to make a tripod more rigid.

Monopods

A monopod is a single pole on which a camera is mounted. Monopods are useful for keeping the camera steady for location work when a tripod is too bulky or difficult to use; however, the use of a monopod is not advisable when using large, heavy cameras or when shutter speeds below about 1/15 second are used. Standing or kneeling with a monopod braced against your body or leg provides a camera the extra support and steadiness required for it to be an effective tool (fig. 5-4).

Clamps

Another practical way to support your camera is to use one of the many clamps available for this purpose. A camera clamp has a mount that screws into the tripod hole or socket on the camera and has jaws that can be clamped to a convenient object. Camera support clamps can be attached to furniture, doors, posts, fences, and other firm anchor points. There are even clamps with suction cups for mounting cameras on smooth, flat surfaces, such as a window.

PHOTOGRAPHIC COMPOSITION

Photographic composition is *the pleasing arrangement of subject matter elements within the*

Figure 5-4.—Using a monopod.

picture area. Creative photography depends foremost on the photographer's ability to see as the camera sees because a photograph does not reproduce a scene quite the way we see it. The camera sees and records only a small isolated part of the larger scene, reduces it to only two dimensions, frames it, and freezes it. It does not discriminate as we do. When we look at a scene we *selectively* see only the important elements and more or less ignore the rest. A camera, on the other hand, sees all the details within the field of view. This is the reason some of our pictures are often disappointing. Backgrounds may be cluttered with objects we do not remember, our subjects are smaller in the frame or less striking than we recall, or the entire scene may lack significance and life.

Good pictures are seldom created by chance. To make the most of any subject, you must understand the basic principles of composition. The way you arrange the elements of a scene within a picture, catch the viewer's attention, please the eye, or make a clear statement are all qualities of good composition. By developing photographic composition skills, you can produce photographs that suggest movement, life, depth, shape, and form, recreating the impact of the original scene.

How are photographic composition skills developed? You look, you study, you practice. Every time you take a picture, look all around within the viewfinder. Consider the way each element will be recorded and how it relates to the overall composition.

You must become thoroughly familiar with the camera and learn how the operation of each control alters the image. Experiment with the camera and look at the results carefully to see if they meet your expectations. With experience and knowledge of your equipment, you begin to “think through your camera” so you are free to concentrate on composition. Devote serious study to the principles of good composition. Study books and magazine articles on composition. You should analyze various media: motion pictures, TV, magazines, books and newspapers, and evaluate what you see. What is good about this picture or that TV image? What is bad about it? What principles of good composition could you apply in a different way to make the picture better.

Good or correct composition is impossible to define precisely. There are no hard-and-fast rules to follow that ensure good composition in every photograph. There are only the principles and elements that provide a means of achieving *pleasing* composition when applied properly. Some of these principles and elements are as follows:

- Center of interest
- Subject placement
- ◆ Simplicity
- ◆ Viewpoint and camera angle
- ◆ Balance
- Shapes and lines
- Pattern
- Volume
- Lighting
- Texture
- ◆ Tone
- ◆ Contrast
- ◆ Framing
- Foreground
- ◆ Background
- ◆ Perspective

As you study these principles of composition, you should soon come to a realization that some are very similar and overlap one another a great deal.

Because all or most of these principles must be considered and applied each time you take a picture, it

may all seem quite confusing at first. With experience you can develop a sense of composition, and your consideration and application of the principles will become almost second nature. This is not to suggest that you can allow yourself to become complacent or careless in the application of the principles of composition. Doing so will be immediately obvious because the results you produce will be snapshots, not professional photographs.

The principles of composition that follow apply equally to both still and motion media photography.

CENTER OF INTEREST

Each picture should have only one principal idea, topic, or *center of interest* to which the viewer's eyes are attracted. Subordinate elements within the picture must support and focus attention on the principal feature so it alone is emphasized.

A picture without a dominant center of interest or one with more than one dominant center of interest is puzzling to a viewer. Subsequently, the viewer becomes confused and wonders what the picture is all about. When the picture has one, and only one, dominant “point of interest,” the viewer quickly understands the picture.

NOTE: “Point of interest,” as used here, has the same meaning as center of interest; however, using the term *point of interest* prevents giving the impression that the center of interest should be located in the center of the picture.

The specific topic, idea, or object to be portrayed must be set in your mind as you prepare to take a picture. When there is nothing in the picture to attract attention to a particular area or object, the eyes wander throughout the scene. The center of interest may be a single object or numerous ones arranged so attention is directed to one definite area.

When the center of interest is a single object that fills most of the picture area or one that stands out boldly, such as a white sail against a background of dark water, attention is attracted immediately to it. As may be expected, not all subjects are as simple to arrange or as bold and impressive.

A photographer usually has at his or her disposal many factors or elements that can be used and arranged within the picture area to draw or direct attention to the primary idea of the picture. Some of these elements are lines, shapes, human figures, tone, and texture.

Human figures attract attention more strongly than almost any other subject matter and unless they are the

Figure 5-5.—Principle of thirds.

main object of the photograph should probably be kept out of the picture; for instance, a photograph showing a person standing at some distance in front of a building may leave the observer wondering whether the person or the building is the primary subject. When people are included in a scene for comparative size of objects or just for atmosphere, keep them from looking directly at the camera. When people look at the camera and therefore at the viewer of the picture, the viewer tends to return their gaze by looking directly back into their eyes. When they are not the intended point of interest, we miss the statement and purpose of the picture. When people are subordinate elements within the picture and they are looking in a direction other than at the camera, the viewer's attention is directed from the people to what *they are* looking at, which *should* be the center of interest; for example, when people are grouped around a piece of machinery that is the center of interest of the picture, have them look at the machine, rather than the camera.

SUBJECT PLACEMENT

Sometimes good composition is obtained by placing the center of interest in the geometrical center of the picture; it is generally not a good idea to place it there. Too frequently it divides the picture into equal halves and makes the picture uninteresting and difficult to balance. By dividing the picture area into thirds, both vertically and horizontally, and locating the center of interest at one of the intersections of the imaginary lines, you can usually create a feeling of balance to the composition (fig. 5-5).

In photographic composition there are two general guides for determining the best location for the center of interest. *The first is the principle of thirds. The other is dynamic symmetry.* In the principle of thirds, the intersection of lines that divide the picture area into

Figure 5-6.—Dynamic symmetry.

thirds are marked by O's. These intersections are good locations for the center of interest in most photographs. Notice we said *THE* center of interest. Remember, have only one center of interest to a picture—keep it simple. The principle of dynamic symmetry is a similar idea. A good location for the center of interest is found by drawing or imagining a diagonal line from one corner to an opposite corner. Then, draw a second line perpendicular to the first from a third corner (fig. 5-6). The intersections of the lines are the location for the center of interest.

SIMPLICITY

Simplicity is the key to most good pictures. The simpler and more direct a picture is, the clearer and stronger is the resulting statement. There are several things to be considered when we discuss simplicity. First, select a subject that lends itself to a simple arrangement; for example, instead of photographing an entire area that would confuse the viewer, frame in on some important element within the area. Second, select different viewpoints or camera angles. Move around the scene or object being photographed. View the scene through the camera viewfinder. Look at the foreground and background. Try high and low angles as well as normal eye-level viewpoints. Evaluate each view and angle. Only after considering all possibilities should you take the picture. See beyond and in front of your subject. Be sure there is nothing in the background to distract the viewer's attention from the main point of the picture. Likewise, check to see there is nothing objectional in the foreground to block the entrance of the human eye into the picture.

A last point of simplicity—*tell only one story*. Ensure there is only enough material in the picture to convey

one single idea. Although each picture is composed of numerous small parts and contributing elements, none should attract more of the viewer's attention than the primary object of the picture. The primary object is the reason the picture is being made in the first place; therefore, all other elements should merely support and emphasize the main object. Do not allow the scene to be cluttered with confusing elements and lines that detract from the primary point of the picture. Select a viewpoint that eliminates distractions so the principal subject is readily recognized. When numerous lines or shapes are competing for interest with the subject, it is difficult to recognize the primary object or determine why the picture was made.

VIEWPOINT AND CAMERA ANGLE

The proper viewpoint or camera angle is an important factor in good composition. Repositioning your subject within the viewfinder frame and changing the camera viewpoint or camera angle are two simple ways of controlling composition.

Photographing from a different viewpoint or camera angle can often add drama and excitement or even bring out an unusual aspect of a subject. Most of the subjects you photograph are three-dimensional and should be photographed from an angle (to the right or left of and/or from higher or lower than the subject) that allows the viewer to see more than one side of the subject. The photographer should study the subject from different sides and angles. Walk around the subject and look at it from all viewpoints. See it from elevated and low positions as well as from eye level to find the best composition. This greatly assists in composing the subject for the best balance and helps to select a background that compliments, not distracts from the subject.

The terms *viewpoint* and *camera angle* are often used in conjunction with one another and sometimes used interchangeably. They can also have different meanings depending on how they are applied. Viewpoint" is the camera position in relationship to the subject. "Camera angle" is the angle in which the camera lens is tilted; for example, a picture of sailors marching, made from ground level with the camera held horizontal with reference to the ground, may be referred to as a "low viewpoint" (or camera position); however, when this picture is made, again from ground level, but with the camera pointed up, it may be referred to as a "low camera angle." Likewise, a picture made from an elevated or high position, with the camera again held horizontal with reference to the ground, or even pointed

straight down, can be referred to as a "high viewpoint"; however, if the camera is not held horizontal to the ground or pointed straight down, but pointed at some angle between horizontal and vertical, the camera position could be referred to as a "high camera angle."

Eye-Level Shots

With the camera held horizontal, eye-level shots are usually made at a height of about 5 1/2 feet, the height from which the average adult sees, and with the camera horizontal. With the camera held at eye level but pointed up or down, the camera position changes and you have either a low or high camera angle, respectively.

Low Viewpoint and Low Camera Angle

Low viewpoints and low camera angles can add emphasis and interest to many ordinary photographs. A low viewpoint can be used to distort scale or add strength to a picture or to emphasize certain elements within the picture. A low camera angle is achieved when the camera angle is located below the point of primary interest and pointed upward. Low angles tend to lend strength and dominance to a subject and dramatize the subject. Low angle shots are used when dramatic impact is desired. This type of shot is very useful for separating the subject from the background, for eliminating unwanted foreground and background, and for creating the illusion of greater size and speed (fig. 5-7).

High Viewpoint and High Camera Angle

High viewpoints and high camera angles help orient the viewer, because they show relationships among all elements within the picture area and produce a psychological effect by minimizing the apparent strength or size of the subject (fig. 5-8).

BALANCE

Balance in photographic composition is a matter of making pictures look harmonious. Each element in a picture has a certain amount of value in respect to all the other elements. Every tone, mass, shape, tree, rock figure, building, line, or shadow contributes a certain amount of weight that must be arranged correctly in the composition to give the impression of balance. The subject placement within the picture area is the factor that must be carefully considered.

Composition is kept in balance by two different methods: symmetrical, or formal, balance and asymmetrical, or informal, balance.

302.293

Figure 5-7.—Low viewpoint and low camera angle.

Symmetrical, or Formal, Balance

Symmetrical, or formal, balance in a photograph is achieved when elements on both sides of the picture are of equal weight (fig. 5-9A). The idea of formal balance can be related to a seesaw. When there are two equally

weighted objects on the seesaw and they are equidistant from the pivot point, or fulcrum, the board will be in balance.

Pictures with formal balance may look static and unexciting; however, they do present an air of dignity.

JO1(SW) Herkovitz
302.294

Figure 5-8.—High viewpoint and high camera angle.

Formal balance does not always mean a picture has to be symmetrical. Symmetrical pictures, in which both sides are exactly the same, are produced only when you want a special effect; therefore, they are not often produced. A variation of symmetrical balance deals with

the seesaw in perspective. The forces or weights are presumed to be approximately equal; but, the imaginary pivot point is set deep into the picture space. With this variation to symmetrical balance, a more interesting photograph is usually created (fig. 5-9B).

Figure 5-9A.—Symmetrical, or formal, balance.

237.214

Figure 5-9B.—Symmetrical, or formal, balance.

302.41

PHC Chet King
302.42

Figure 5-10.—Asymmetrical, or Informal, balance.

Asymmetrical, or Informal, Balance

Asymmetrical, or informal, balance is usually much more interesting than symmetrical balance. In asymmetrical balance the imaginary central pivot point is still presumed to be present; however, instead of mirror images on each side of the picture area, the subject elements are notably different in size, shape, weight, tone, and placement. Balance is established by equalizing the element forces in spite of their differences.

Asymmetrical balance is introduced when the presumed weight of two or more lighter objects is equalized by a single heavier object placed on the other side of the imaginary pivot point (fig. 5-10). Asymmetrical balance is more difficult to achieve than symmetrical balance, because of the problem of establishing relative weight values for dissimilar elements within the picture area as well as presenting some form of stability.

Aspects of Balance

There are many other factors to consider in order to make pictures appear balanced. Some of these are as follows:

- An object far from the center of the picture seems to have more weight than one near the center.

- Objects in the upperpart of a picture seem heavier than objects of the same size in the lower part of a picture.

- Isolation seems to increase the weight of an object.

- Intensely interesting objects seem to have more compositional weight.

- Regular shapes seem to have more weight than irregular shapes.

- Elements on the right side of an asymmetrical picture appear to have more weight than elements of the same size on the left side of the picture.

- The directions in which figures, lines, and shapes appear to be moving within the picture area are important to balance; for example, a person may be walking in a direction, or his eyes may be looking in a direction, or the shape of some element creates a feeling of movement. When the feeling of direction is present within a scene, it tends to upset the balance if judged on the size of the subject alone.

Understanding the factors required to create pictorial balance is essential for you to produce good pictures. To gain this understanding, you can continually test your feelings for balance as you look through your camera viewfinder. Once you gain an understanding of the principles of pictorial balance, achieving balance in your photographs becomes an easy process.

302.295

Figure 5-11.—Silhouettes emphasize shape.

SHAPES AND LINES

Shapes and lines are important elements in photographic composition. When properly used, shapes and lines can create a desired effect. As a photographer, you usually have control over the way shapes and lines are used in your pictures.

Shape

Shape is a two-dimensional element basic to picture composition and is usually the first means by which a viewer identifies an object within the picture. *Form* is

the three-dimensional equivalent of shape. Even though shape is only two-dimensional, with the proper application of lighting and tonal range, you can bring out form and give your subjects a three-dimensional quality. Lighting can also subdue or even destroy form by causing dark shadows that may cause several shapes to merge into one.

Shapes can be made more dominant by placing them against plain contrasting backgrounds; for example, consider again the white sail against the dark water background. The greatest emphasis of shape is achieved when the shape is silhouetted (fig. 5-11), thus

PH1 Art Legare
302.296

Figure 5-12.—Leading lines.

eliminating other qualities of the shape, such as texture and roundness, or the illusion of the third dimension.

Lines

Lines can be effective elements of composition, because they give structure to your photographs. Lines can unify composition by directing the viewer's eyes and attention to the main point of the picture or lead the eyes from one part of the picture to another. They can

lead the eyes to infinity, divide the picture, and create patterns. Through linear perspective, lines can lend a sense of depth to a photograph. (Linear perspective causes receding parallel lines to appear to converge in the picture. This allows you to create an illusion of depth in your pictures.)

The viewer's eyes tend to follow lines into the picture (or out of the picture) regardless of whether they are simple linear elements such as fences, roads, and a

PH2(AC) Mark Kettenhofen
302.297

Figure 5-13.—Diagonal lines convey a feeling of dynamic action.

row of phone poles, or more complex line elements, such as curves, shapes, tones, and colors. Lines that lead the eye or direct attention are referred to as *leading lines*. A good leading line is one that starts near the bottom corner of the scene and continues unbroken until it reaches the point of interest (fig. 5-12). It should end at this point; otherwise, attention is carried beyond the primary subject of the photograph. The apparent direction of lines can often be changed by simply changing viewpoint or camera angle.

Vertical, diagonal, horizontal, and curved lines create different moods. Vertical lines communicate a

sense of strength, rigidity, power, and solidarity to the viewer. On the other hand, horizontal lines represent peace, tranquillity, and quietness. A generally accepted practice is to use a vertical format for pictures having predominantly vertical lines and horizontal format for pictures having predominantly horizontal lines. Again, this is a *generally accepted practice*, NOT a rule.

Diagonal lines represent movement, action, and speed. A picture with diagonal lines conveys a feeling of dynamic action even when the subject is static (fig. 5-13). Curved lines present a sense of grace,

PH2 Frazier
302.298

Figure 5-14.—Use of curved lines in photographic composition.

smoothness, and dignity to a photograph (fig. 5-14). The most common curved line is the S curve.

Lines are not only present in the shape of things but can be created by arranging several elements within the picture area so they form lines by their relationship with one another.

PATTERN

Creating your pictures around repeating elements or patterns provides picture unity and structure. Pattern repetition creates rhythm that the eyes enjoy following (fig. 5-15). When lines, shapes, and colors within a picture occur in an orderly way (as in wallpaper), they create patterns that often enhance the attractiveness of photographs. Pattern, like texture, is found almost everywhere. It can be used as the primary subject but is most often used as a subordinate element to enhance composition. When pattern is used as a supporting

element, it must be used carefully so it does not confuse or overwhelm the viewer. Pictures that are purely pattern are seldom used, because they tend to be monotonous. Patterns should be used to strengthen and add interest to your subject.

Shape is the most common and powerful pattern element. Repeated lines, tone, and color can also provide unity to your composition and combinations of these create interesting pictures. Triangles, squares, and circles are the basic shapes to look for in a pattern. Triangles and squares are usually static but can be placed to create a tension-filled, dynamic effect. Circles and curves are pleasing pattern shapes.

VOLUME

When photographing most subjects, you face the problem of how to symbolize three-dimensional objects in a two-dimensional picture. The solution becomes

PHAN A. J. Seely
302.299

Figure 5-15.—Shapes used in composition.

simple when a distinction is made between the two different ways three-dimensional objects appear: as positive, or occupied space (volume) or as negative, or unoccupied space.

If you make a picture to show the entire machine shop aboard a repair ship using only one powerful flash

unit placed at the camera, you only *symbolize* empty or negative space; however, a sense of depth is provided because of increasing darkness toward the back of the shop. Occupied or positive space (the machines) is front-lighted and appears shadowless and flat. On the other hand, if you use a series of lights along the sides

of the machine shop to sidelight the machines, shadows are cast at their sides and occupied or positive space appears three-dimensional; however, since all the machines, both near and far, are now lighted the same, you do not create a sense of depth, and empty or negative space appears flat. For the best picture of the machine shop, you should light the machines in a way that the three-dimensional form is represented, while creating a sense of depth by reducing the intensity of illumination toward the back of the shop.

LIGHTING

Lighting is also an important creative element of composition. By controlling the light and directing it where you want it, you can subdue objects or distracting elements in the scene to give more emphasis to the main point of interest.

For good picture composition, you must develop an awareness of how changes in lighting can affect the appearance of things around you. Light and shadows can be used in composition to create mood, to draw attention to an area, to modify or distort shape, or to bring out form and texture in the subject.

Shadows are a key to apparent form in photographs. Without shadows, the subject records without form, curvature, or texture, appearing flat and lifeless. This does not mean that shadows must be harsh and black to achieve the effects of form, curvature, and texture. They may be soft, yet of sufficient density to show the most delicate roundness and form. Generally, harsh, black shadows are undesirable in a photograph due to the loss of detail in them. From a compositional standpoint, black shadows can be very useful in balancing a scene and directing attention to the point of interest. Harsh shadows can also be excellent for emphasizing texture and form, for creating interesting patterns, and for directing attention to the main point of interest; however, the same elements can also obscure detail and reduce form. When the lighting is harsh, such as on a clear, sunny day, shadows have sharply defined edges and are probably very dark, sometimes to the point that they appear stronger than the primary subject and attract attention to themselves.

TEXTURE

Texture helps to emphasize the features and details in a photograph. By capturing “texture” of objects being photographed, you can create form.

When people observe a soft, furry object or a smooth, shining surface, they have a strong urge to touch it. You can provide much of the pleasure people get from the feel of touching such objects by rendering texture in your pictures. Texture can be used to give realism and character to a picture and may in itself be the subject of a photograph. When texture is used as a subordinate element within the picture, it lends strength to the main idea in the photograph. It usually takes just a little different lighting or a slight change in camera position to improve the rendering of texture in a picture. When an area in a photograph shows rich texture, the textured area usually creates a form or shape; therefore, it should be considered in planning the photograph (fig. 5-16).

TONE

Tone is probably the most intangible element of composition. Tone may consist of shadings from white-to-gray-to-black, or it may consist of darks against lights with little or no grays. The use of dark areas against light areas is a common method of adding the feeling of a third dimension to a two-dimensional black-and-white picture. The interaction of light against dark shades in varying degrees helps to set the mood of a composition. A picture consisting of dark or somber shades conveys mystery, intrigue, or sadness. When the tones are mostly light and airy, the picture portrays lightness, joy, or airiness.

CONTRAST

Contrast in photographic composition is an effective means of directing the viewer's attention to the center of interest. Positioning of subject elements to create contrast gives them added emphasis and directs the viewer's attention.

When we speak of contrast as it relates to composition, we are referring to both tonal contrast, as in black-and-white photography, and color contrast as it relates to color photography. In black-and-white photography, contrast is the difference in subject tones from white-to-gray-to-black or from the lightest tone to the darkest tone. In color photography different colors create contrast.

PH2 J. Finnigan
302.300

Figure 5-16.—Photograph emphasizing texture.

Tonal Contrast

In black-and-white photography, contrast is considered either *high*, *normal*, or *low*. A high-contrast scene or photograph consists primarily of white and black with few or no middle gray tones. A black sailor in a white uniform against a light background is an example of a high-contrast (contrasty) scene. Most scenes you photograph have normal contrast. There will probably be elements within the scene that are very light or white, some that are very dark or black, and many tones or colors that reproduce as various tones of gray. A low-contrast (flat) scene has colors or tones in which highlights and shadows have very little difference in densities. In other words, all colors or tones within the scene are very similar in appearance. A white sailor in a white uniform against a light background is an example of a scene with low contrast.

In black-and-white photography, high contrast conveys a sense of hardness and is characteristic of

strength and power. Low contrast conveys a sense of softness and is characteristic of gentleness and mildness.

Color Contrast

Color contrast is an effective compositional element in color photography, just as tone is in black-and-white photography. Colors with opposite characteristics contrast strongly when placed together. Each color accentuates the qualities of the other and makes the color images stand out dramatically. Color contrast is enhanced when you create the contrast of detail against mass. An example is a single, bright, red flower in a clear, glass vase photographed against a bright, green background.

Cold colors (bluish) and warm colors (reddish) almost always contrast. Cold colors recede, while warm colors advance. Light colors contrast against dark ones, and a bold color offsets a weak color.

PH2 Neil Crews
302.301

Figure 5-17.—Low-key scene.

LOW- AND HIGH-KEY SCENES.—When a scene contains mostly dark tones or colors, it is low key (fig. 5-17). When the scene contains mostly light tones, it is high key (5-18). Low-key and high-key pictures convey mood and atmosphere. Low key often suggests seriousness and mystery and is often used in horror pictures, such as a dark-granite castle in a thunderstorm. High key creates a feeling of delicacy and lightness. A photograph of a fair-skinned, blond-haired mother dressed in a white gown against a light background nursing her baby is a good subject for a high-key picture.

HIGH- AND LOW-KEY COLORS.—High-key color pictures contain large areas of light desaturated colors (pastels) with very few middle colors or shadows. Intentionally overexposing color film (exposing for the shadows) helps to create a high-key effect.

A low-key effect is created when the scene is dominated by shadows and weak lighting. Low-key pictures tend to have large areas of shadow, few highlights, and degraded colors. Naturally dark subjects are best for low-key pictures. Low-key color pictures can be induced by exposing color film for the highlights.

FRAMING

Framing is another technique photographers use to direct the viewer's attention to the primary subject of a picture. Positioned around the subject, a tree, an archway, or even people, for example, can create a frame within the picture area. Subjects enclosed by a frame become separated from the rest of the picture and are emphasized. Looking across a broad expanse of land or water at some object can make a rather dull uninteresting view. Moving back a few feet and framing the object between trees improves the composition.

An element used as a frame should not draw attention to itself. Ideally, the frame should relate to the theme of the picture; for example, a line of aircraft parked on the flight line framed by the wing and prop of another aircraft.

Not only is framing an effective means of directing the viewer's attention, it can also be used to obscure undesirable foregrounds and backgrounds. The illusion of depth can be created in a picture by the effective use of framing (fig. 5-19).

FOREGROUND

A large percentage of otherwise good pictures is ruined, because they include unnecessary or distracting foreground. This common fault can result from the photographer standing too far away from their subject when they *take* a picture, or the fact that normal focal length or standard lenses cover a relatively wide angle of view.

Undesirable foreground can be eliminated by moving in closer to the subject, by making pictures with a longer than standard focal-length lens, or by changing viewpoint or camera angle. Many already existing pictures can be improved by enlarging only a section of the negative and by cropping out meaningless or distracting foreground. In most cases, the foreground should be sharply focused and of sufficient depth to furnish substantial support for the subject. No object in the foreground should ever be so prominent that it distracts from the subject. You should clear the foreground of items that have no connection with the

picture. The ultimate example of carelessness on the part of the photographer is to leave his or her camera case where it shows in the picture. Generally, the foreground contains the leading line that is the line that leads the eye into the photograph and toward the point of interest. Whether this line is an object or series of objects or shadows, it should be sharply focused. A fuzzy, out-of-focus foreground usually irritates the senses and detracts from emphasis on the subject matter.

BACKGROUND

The background is almost as important an element in good composition as the camera angle. Too often it is overlooked when composing a scene since the photographer normally gives so much attention to the subject. Be particularly observant of the background to see that it contains nothing distracting. A tree or pole that was unnoticed in the distance behind a person when composing the scene may appear in the photograph to

be growing out of his or her collar or supporting his or her head.

The background should be subordinate to the main subject in both tone and interest. It should also make the subject stand out and present it to best advantage. Unsharpness and blur are effective ways for separating the subject from the background. Unsharpness can be accomplished by using a relatively large *f/stop* to render the background out of focus. In the case of subjects in motion, the subject can be pictured sharply and the background blurred by panning the subject (fig. 5-20). Occasionally, you may want to reverse these effects and record the subject unsharp or blurred and the background sharp. This is done to create the impression of the subject being closer to the viewer or to express motion by holding the camera still as you use a shutter speed that is too slow to “stop” the motion.

PERSPECTIVE

Perspective refers to the relationship of imaged objects in a photograph. This includes their relative positions and sizes and the space between them. In other words, perspective in the composition of a photograph is the way real three-dimensional objects are pictured in a photograph that has a two-dimensional plane. In photography, perspective is another illusion you use to produce photographs of quality composition.

When you are making pictures, the camera always creates perspective. Because a camera automatically produces perspective, many novice photographers believe there is no need to know much about it. This attitude is far from correct. When you know the principles of perspective and skillfully apply them, the photographs you produce show a good rendition of the subject's form and shape, and the viewer is given the sensation of volume, space, depth, and distance. Additionally, the photographer can manipulate perspective to change the illusion of space and distance by either expanding or compressing these factors, therefore providing a sense of scale within the picture.

Linear Perspective

The human eye judges distance by the way elements within a scene diminish in size, and the angle at which lines and planes converge. This is called *linear perspective*.

The distance between camera and subject and the lens focal length are critical factors affecting linear perspective. This perspective changes as the camera position or viewpoint changes. From a given position,

changing only the lens focal length, and not the camera position, does not change the *actual* viewpoint, but may change the *apparent* viewpoint.

The use of different focal-length lenses in combination with different lens-to-subject distances helps you alter linear perspective in your pictures. When the focal length of the lens is changed but the lens-to-subject distance remains unchanged, there is a change in the image size of the objects, but no change in perspective. On the other hand, when the lens-to-subject distance and lens focal length are both changed, the relationship between objects is altered and perspective is changed. By using the right combination of camera-to-subject distance and lens focal length, a photographer can create a picture that looks deep or shallow. This feeling of depth or shallowness is only an illusion, but it is an important compositional factor.

Using a short-focal-length lens from a close camera-to-subject distance, or viewpoint, produces a picture with greater depth (not to be confused with depth of field) than would be produced with a standard lens. Conversely, using a long-focal-length lens from a more distant viewpoint produces a picture with less apparent depth.

Rectilinear Perspective

Most lenses produce rectilinear perspective that are typical of what the human eye sees. This is to say that lines that are straight in the subject are reproduced straight in the picture. Most pictures are made with rectilinear lenses.

Fisheye lenses and the lenses used on panoramic cameras produce a false perspective. A panoramic lens produces panoramic or cylindrical perspective. In other words, all straight horizontal lines at the lens axis level are recorded as straight lines, and all other straight horizontal lines either above or below the lens axis level are reproduced as curved lines. The other false perspective is produced by a fisheye lens in which all straight lines in the subject are imaged as curved lines toward the edges of the picture.

Vanishing Point Perspective

In vision, lines that are parallel to each other give the sensation of meeting at vanishing points. When parallel lines, either horizontal or vertical, are *perpendicular* to the lens axis, the vanishing points are assumed to be at infinity. Other lines, those which are *parallel* to the lens axis, and all other parallel lines at all other angles to the lens axis meet at definable vanishing

PHC Jeff Hilton
302.303

Figure 5-21.—Vanishing point perspective.

points. Thus lines that are parallel to the lens axis, or nearly parallel, start in the front of the picture and meet at vanishing points within the picture or at finite points outside the picture (fig. 5-21).

Height Perspective

The place where the base of an object is located on the ground in a picture is a clue to its distance from the camera viewpoint; for example, in a landscape scene, the ground or ground plane rises toward the horizon. The higher up in the ground area of the picture (up to the horizon) that the base of an object is located, the further

away it seems from the viewpoint and the greater its height perspective.

Overlap Perspective

Another clue to distance in a photograph is overlap perspective. When subjects within the picture are on about the same line of sight, those objects closer to the camera viewpoint overlap more distant objects and partially hide them. It is obvious to the viewer that the partially obstructed object is behind the unobstructed object. This overlap is repeated many times within the picture and gives the viewer a sense of depth and a perception of the relative distance of objects.

PH3 Joan Zopf
302.304

Figure 5-22.—Dwindling size perspective.

Dwindling Size Perspective

Through the experience of vision, you are aware of the size of many common objects, such as people, trees, cars, buildings, and animals; for example, you are aware that most adults are about 5 to 6 feet tall; therefore, when two people are shown in a picture and one appears twice as tall as the other, you cannot assume that one is in reality taller than the other. Instead you assume the taller person is closer and the shorter person farther away from the camera viewpoint. In this same manner, you make a size relationship evaluation of all familiar objects. Thus you can make a distance determination from this size relationship evaluation. The farther away an object is from the viewpoint, the smaller it appears; therefore, when subjects of familiar size are included in a photograph, they help to establish the scale of the picture (fig. 5-22). Scale helps the viewer determine or visualize

the actual size or relative size of the objects in the picture.

Volume Perspective

When a subject is lighted with very diffused light, the three-dimensional form or volume of the subject is difficult to perceive because of the lack of distinct shadows. If, on the other hand, subjects are lighted with strong directional light from angles that cause part of the subject to be fully lighted and other parts to be in shadow, a visual clue of the subject's form or volume is provided. When a number of such objects are included within the picture area, the perception of form, volume, and depth is increased. When front or side lighting is used, the length, depth, and shape of the shadows cast on the ground provide a perspective of each object's volume. Also, the distance between shadows cast on the

302.305

Figure 5-23.—Atmospheric perspective.

ground helps you to perceive the overall depth of the scene.

Atmospheric Perspective

For all practical purposes, air is transparent. For most photography, this is fundamentally true; however, when pictures are made of subjects at great distances, the air is actually less than fully transparent. This is because air contains very fine particles of water vapor, dust, smoke, and so on. These particles scatter light and change its direction. The presence of scattering shows distant subjects in pictures as having a veil or haze. The appearance or effect of this scattering is proportional to the distance of the objects from the viewpoint. The greater the distance, the greater the amount of veiling or haze (fig. 5-23). The effects of this scattering of light are additive, but vary with atmospheric conditions.

In atmospheric perspective several factors must be considered:

- ◆ **Contrast**—The luminance of each object in a scene is a direct result of the objects reflective quality and the amount of light falling on it. When objects are far away, light from highly reflective objects is scattered; therefore, when viewed from a distance (or imaged on a print), the darker portions of these distant objects do not appear as dark and the contrast is reduced. When there are objects both near and far from the camera, the difference in contrast provides a perception of distance.
- ◆ **Brightness**—The particles in air that scatter light are also illuminated by the sun. This causes an increase in the overall brightness of the objects seen. This increase in luminance, coupled with a loss of contrast, causes objects in the distance to be seen and

photographed as lighter in color than they would be at a closer distance.

- **Color saturation**—The scattering of light not only affects contrast and brightness but also color saturation.

Color is defined by three qualities: *hue* (the actual wavelength), *saturation* (intensity or chroma), and *brightness* (reflective). A pure hue is fully saturated or undiluted. When a hue is desaturated or diluted, it is no longer pure but has gray intermingled with it. The actual colors of a distant scene appear to have less color saturation, because the light is scattered and also because of the overall presence of the desaturated (diluted) blue light of aerial haze. The original scene colors appear less saturated or pure when seen or photographed from a distance than from close-up; therefore, color saturation or desaturation allows the viewer to perceive distance in a color photograph.

- **Sharpness**—Because of atmospheric haze, there is a loss of image sharpness or definition in distant objects. This loss of sharpness is caused both by the lowering of contrast and the scattering of light. The loss of sharpness contributes to a sense of distance. This can be enhanced by setting the far limit of the lens depth of field just short of infinity. This procedure throws the most distant objects slightly out of focus. This combined with the other effects of aerial perspective intensifies the sense of distance.

PHOTOGRAPHIC LIGHTING

In this discussion of lighting, the basic lighting techniques used by photographers are presented. Lighting used primarily with a certain segment of photography, such as motion picture, TV, portrait, and studio, are discussed in the chapters relevant to that particular subject.

OUTDOOR LIGHTING

As a photographer, you work with light to produce quality pictures. The color, direction, quantity, and quality of the light you use determines how your subjects appear. In the studio, with artificial light sources, you can precisely control these four effects; however, most of the pictures you make are taken outdoors. Daylight and sunlight are not a constant source, because they change hourly and with the weather, season, location, and latitude. This changing daylight can alter the apparent shapes, colors, tones, and forms of a scene. The color of sunlight changes most

rapidly at the extreme ends of the day. Strong color changes also occur during storms, haze, or mist and on blue wintery days. The direction of light changes as the sun moves across the sky. The shape and direction of shadows are altered, and the different directions of sunlight greatly affect the appearance of a scene.

The quality of sunlight depends on its strength and direction. Strong, direct sunlight is “hard” because it produces dark, well-defined shadows and brilliant highlights, with strong modeling of form. Sunlight is hardest on clear summer days at noon. Strong sunlight makes strong colors more brilliant, but weak colors pale. Sunlight is diffused by haze, mist, and pollution in the air. This diffused or reflected light is softer; it produces weak, soft shadows and dull highlights. Directionless, diffused sunlight is often called “flat” lighting because it produces fine detail but subdues or flattens form. Weak, directionless sunlight provides vibrant, well-saturated colors.

Frontlighting

The old adage about keeping the sun at your back is a good place to continue our discussion of outdoor lighting. The type of lighting created when the sun is in back of the photographer is called frontlighting. This over-the-shoulder lighting was probably the first photographic advice you ever received. This may seem to be a universal recipe for good photography. But it is not. The case against over-the-shoulder lighting is it produces a flattened effect, doing nothing to bring out detail or provide an impression of depth. The human eye sees in three dimensions and can compensate for poor lighting. A photograph is only two-dimensional; therefore, to give an impression of form, depth, and texture to the subject, you should ideally have the light come from the side or at least at an angle.

Side Lighting

As you gain experience with various types of outdoor lighting, you discover that interesting effects can be achieved by changing the angle of the light falling on your subject. As you turn your subject, change the camera viewpoint, or wait for the sun to move, the light falls more on one side, and more shadows are cast on the opposite side of the subject. For pictures in which rendering texture is important, side lighting is ideal.

Look at a brick wall, first in direct front sunlight and then in side lighting. Direct, front sunlight shows the pattern of the bricks and mortar in a flat, uninformative

PHC Ron Bayles
302.88

Figures 5-24.--Comparison of front and side lighting.

way, but side lighting creates shadows in every little crevice (fig. 5-24). The effect increases as the light is more parallel with the wall until long shadows fall from the smallest irregularity in the brickwork. This can give an almost 3-D effect to a photograph.

Side lighting is particularly important with black-and-white photography that relies on gray tones, rather than color, to record the subject. Shadows caused by side lighting reveal details that can create striking pictures from ordinary objects that are otherwise hardly worth photographing in black and white. Anything that has a noticeable texture--like the ripples of sand on a beach, for example--gains impact when lit from the side. Landscapes, buildings, people, all look better when sidelighted.

This applies to color photography as well. Color gives the viewer extra information about the subject that may make up for a lack of texture in frontlighting, but often the result is much better when lit from the side.

Pictures made with side lighting usually have harsh shadows and are contrasty. To lighten the shadows and reduce the contrast, you may want to use some type of reflector to direct additional skylight into the shadow areas or use fill-in flash, whichever is more convenient.

Backlighting

When the sun is in front of the photographer, coming directly at the camera, you have what is referred to as backlighting; that is, the *subject* is backlit. This type of lighting can be very effective for pictures of people outdoors in bright sunlight. In bright sunlight, when

subjects are front-lighted or even sidelighted, they may be uncomfortable and squint their eyes. Backlighting helps to eliminate this problem. Backlighting may also require the use of a reflector or fill-in flash to brighten up the dark shadows and improve subject detail. Backlighting is also used to produce a silhouette effect.

When you use backlighting, avoid having the sun rays fall directly on the lens (except for special effects). A lens hood or some other means of shading the lens should be used to prevent lens flare.

EXISTING LIGHT

Existing light photography, sometimes called available or natural light photography, is the making of pictures by the light that happens to be on the scene. This includes light from table, floor, and ceiling lights, neon signs, windows, skylights, candles, fireplaces, auto mobile headlights, and any other type of light that provides the natural lighting of a scene--except daylight outdoors. (Moonlight is considered existing light.) Existing light then is that type of light found in the home, in the office, in the hangar bay, in the chapel, in the club, in the sports arenas, and so on. Outdoor scenes at twilight or after dark are also existing light situations.

Photography by existing light produces pictures that look natural. Even the most skillfully lighted flash picture may look artificial when compared to a good existing light photograph. With existing light photography, the photographer has an opportunity to make dramatic, creative pictures. Existing light allows the photographer greater freedom of movement because

extra lighting equipment is not required. Subject distance, when not using flash, has no effect on exposure; therefore, you can easily photograph distant subjects that could not otherwise be photographed using flash or some other means of auxiliary lighting. With existing light, you can make pictures that could not be taken with other types of lighting; for example, flash may not be appropriate during a change of command ceremony or chapel service. Not only can the flash disturb the proceedings, but it may not carry far enough to light the subject adequately.

For existing light pictures, your camera should be equipped with a fast lens—at least f/2.8, but preferably about f/1.4. The camera shutter should have a B or T setting, and for exposures longer than about 1/60 second, you need a tripod or other means of supporting the camera.

Because the level of illumination for many existing light scenes is quite low, you may want to consider using a high-speed film. When making pictures with plenty of existing light or when you particularly want long exposures for special effect, you can use a slower film; however, the advantages of high-speed film are as follows:

- Allows you to get adequate exposure for hand-held shots.
- Allows you to use faster shutter speeds to reduce camera and image motion.
- Permits the use of longer focal-length lenses when the camera is hand-held.
- Allows the use of smaller f/stops for greater depth of field.

When you are making existing-light color pictures indoors of scenes illuminated by tungsten light, use a tungsten type of film. When the light for your indoor color pictures is daylight from a window or skylight, use a daylight type of color film or use tungsten film with a No. 85B filter. Always use an exposure meter to calculate your indoor existing light exposure. When a bright window is included in the background, take a closeup meter reading of the subject to prevent the meter from being overly influenced by light from the window.

Pictures made indoors by existing daylight are pleasing to the viewer, because of the soft diffused light and the squint-free expression of your subjects. Open all the window drapes in the room to get the highest level of illumination possible. Pose your subject to allow diffused daylight to fall on the front or side of their face.

Try not to pose your subject in a position where too much of the facial features are in shadow, unless you are trying for a special effect, such as a silhouette. When you photograph your subject in direct nondiffused sunlight coming through a window, you have more light to work with, but the light is contrasty and your subject has a tendency to squint.

Indoor existing light, artificial or otherwise, may be quite contrasty; for example, when your subjects are close to the source of light and well-illuminated, while other areas of the scene are comparatively dark. By turning on all the lights in the room, you can make the illumination more even and provide additional light for exposure and at the same time reduce the scene contrast. The contrast created by some artificial lighting can also be reduced in an average size room by bouncing auxiliary light off the ceiling or by using reflectors. Adding auxiliary bounce lighting or reflectors means you are not making true existing light pictures, but this extra light helps to reduce contrast without spoiling the natural appearance of the scene.

Fluorescent Lighting

Indoor scenes illuminated by fluorescent lights usually appear pleasing and natural in real life; however, color pictures of these same scenes often have an overall color cast that makes them appear unnatural. Fluorescent light emits blue and green light primarily and is deficient in red light. Most color pictures made without a filter under fluorescent light are also deficient in red and have an overall greenish appearance. Used correctly, fluorescent light has some advantages over other types of available light. A room illuminated by fluorescent lamps is usually brighter and more evenly lighted than a room illuminated by tungsten lamps. This higher level of light makes it easier to get enough exposure for your existing light photography and helps record detail that may have been lost in the shadow areas with other types of existing light. When photographing people, however, fluorescent lighting often causes dark shadows under the subject's eyes. These shadows cause the eyes to appear dark and sunk in.

For making color pictures under fluorescent lighting, a negative color film with the appropriate filter is most often your best bet. Color negative film has a wide exposure latitude that permits, to some extent, a variation in exposure without detracting from the quality of the finished print. The greenish effect caused by fluorescent lighting can be partially corrected when the color negatives are printed.

For color slides with fluorescent light, a daylight type of film with the appropriate filter is best. Tungsten film usually produces slides with too much blue or green when made with fluorescent light.

As discussed in chapter 3, the use of filters for color photography helps to overcome the deficiency of red light in fluorescent lamps. Always consult the *Photo-Lab Index* for the best film filter combinations to use.

Pictures Outdoors at Night

Outdoor night scenes usually include large areas of darkness broken by smaller areas of light from buildings, signs, and streetlights. Pictures of outdoor scenes are quite easy to make because good results are obtainable over a wide range of exposures. Using short exposures emphasizes well-lit areas by preserving the highlight detail, while the shadow areas are dark because of underexposure. Long exposures help retain the detail of the dark areas, while highlight detail is lost because of overexposure.

Large, dark areas in night scenes make it difficult to make accurate exposure meter readings from your camera position. The best meter reading results are obtained when you take closeup readings of important scene areas.

Color outdoor pictures at night can be made on either daylight or tungsten-type films. Pictures made on daylight film have a warm, yellow-red appearance. Those made on tungsten film have a colder more natural look; however, both films provide pleasing results, so it is a matter of personal preference which you use.

A good time to make outdoor night color pictures is just before it gets completely dark. At this time, some rich blue (or even orange) is in the sky. This deep color at dusk gives a dramatic background to your pictures. Neon signs, streetlights, and building lights make bright subjects for your pictures. At night, right after it stops raining and everything is still wet, is another good time to make outdoor pictures. The lights in the scene produce many colorful reflections on the wet pavement, adding interest to what may otherwise be a lifeless, dull picture.

Many buildings look rather ordinary in daylight, but at night, they are often interestingly lighted. Try photographing the hangar at night, with the lights on and the hangar doors open. Also, your ship at night, especially a rainy night may make a very striking picture.

Outdoor events that take place at night in a sports stadium are usually well-lighted and make excellent subjects for existing light pictures. Most sports stadiums

(as well as streets) are illuminated by mercury-vapor lamps that look blue-green in color when compared to tungsten lamps. Your best color pictures made under mercury-vapor lighting will be shot on daylight color film, although they will appear bluish green because the lights are deficient in red.

Tips for existing light photography are as follows:

- Carry a flashlight so you can see to make camera settings.
- If you do not have an exposure meter or cannot get a good reading, bracket your exposure.
- Focus carefully; depth of field is shallow at the wide apertures required for existing light photography.
- When you have a scene illuminated by a combination of light sources, use the type of color film recommended for the predominant light source.
- For pictures of fireworks, support your camera on a tripod, focus at infinity, and aim the camera toward the sky area where the display will take place. Open the shutter for several bursts.

ELECTRONIC FLASH LIGHTING

In situations where there is little or no light available, a portable electronic flash unit is an invaluable piece of photographic equipment. With fast films and long exposures, you may be able to shoot existing light pictures, providing your subject remains still long enough. Although you can certainly get better lighting control with elaborate photographic lights, the simplicity and portability of electronic flash is unbeatable.

Electronic flash provides an excellent source of artificial light for exposing black-and-white and color daylight-balanced film. Light from an electronic flash unit (strobe) is characterized by softness, short duration, and color balance, approximating that of daylight.

By measuring the amount of light that actually reaches an object or scene, you can obtain a numerical value that can be converted directly into a flash guide number. The numerical value is the light output rating of an electronic flash unit measured in beam candlepower-seconds (BCPS) or more correctly, effective candlepower-seconds (ECPS).

Every electronic flash unit is assigned a guide number as a measure of its light output or power. The higher the guide number, the greater the light output. Guide numbers for various film speeds are usually

provided with each electronic flash unit. Information packaged with film may also provide guide numbers appropriate to their speed in regard to the various powers of electronic flash units. Manufacturers tend to overrate the power of their electronic flash units. When guide numbers are assigned by the manufacturer, they base the guide number on an average reflective subject and in a room with 10-foot light-colored ceilings. By using these methods, the manufacturers are able to take advantage of the film's exposure latitude.

Like exposure meters, guide numbers are not infallible and some variation from assigned values should be expected. To ensure accuracy of the flash unit, you must check the efficiency of your electronic flash unit to determine your own reliable guide numbers. The steps used to check efficiency are as follows:

1. Place your flash unit (on the camera) exactly 10 feet from a live model who is holding a series of cards—one for each f/stop marked on your lens.
2. Load the camera with the type of film you want to test.
3. Focus the camera on the model and make an exposure at each of the f/stops marked on the cards.

For each exposure, instruct the model to hold up the card marked with the f/stop to be used so it shows noticeably in the picture. Process your film normally, examine the proof sheet or slides carefully, and choose the one shot that best reproduces the model's skin tones. Multiply the f/stop on the card in that picture by 10 (the flash-to-subject distance) and you have the guide number for that particular film and flash unit combination. If, for example, the best exposure was made at f/8, the guide number is 80 ($8 \times 10 = 80$). Once you have determined the correct guide numbers for use with various films, make up a reference chart and attach it to your flash unit.

Correct exposure with electronic flash depends upon four factors:

- The power or light output of the flash unit
- The ISO speed of the film being used
- The flash-to-subject distance
- The f/stop setting

Shutter speed is not a factor since the time of exposure is governed solely by the duration of the flash.

Notice we always speak of *flash-to-subject distance*, never camera-to-subject distance. With all types of artificial illumination (the same as with

sunlight), the only consideration is the amount of light reflected from the subject. The distance between the camera and the subject has no bearing on exposure. When the flash is used off of the camera, the basic f/stop is still calculated with the flash-to-subject distance.

AUTOMATIC ELECTRONIC FLASH UNITS

Most electronic flash units can be operated in an automatic exposure mode. An automatic flash unit eliminates the need to determine the correct f/stop for each flash-to-subject distance, providing the subject is within the flash distance range of the unit.

On the front of an automatic flash unit, a sensor reads the light reflected from the subject that is produced by the flash. When this sensor is satisfied with the amount of light received, it automatically shuts off the flash. The closer the subject is to the lamp, the quicker the sensor shuts off the light.

Some automatic electronic flash units allow you to select two or more apertures to control depth of field. To determine an f/stop in the automatic mode, you can use the calculator dial, located on the unit that is being used. By matching the indicator to an ISO film speed number on the dial, you can use the f/stop within a minimum and maximum distance. Once an f/stop is selected and set, it becomes a constant factor regardless of the flash-to-subject distance, providing it is within the flash distance range of the unit. This feature allows the photographer to move closer to or farther away from a subject without having to calculate an f/stop for each change of flash-to-subject distance (fig. 5-25).

Figure 5-25.—The automatic operating range, using ISO 100 film at f/2.8, is 1.6 to 50 feet.

Figure 5-26.—Manual exposure scale.

When the flash unit is in the manual mode, the f/stop must be changed each time the flash-to-subject distance changes. A scale on the flash unit indicates the proper f/stop to use for the various distances. To determine the flash-to-subject distance for on-camera flash, focus on the subject and read the distance directly from the focusing ring on the camera. Figure 5-26 indicates with ISO 100 film at full power the proper aperture setting at 10 feet is between f/11 and f/16.4 feet is f/32, 40 feet is f/2.8, and so forth.

SINGLE FLASH

The majority of your indoor photographs will be produced using a single-flash unit. Numerous reenlistments, frockings, and promotion ceremonies are conducted indoors where the lighting conditions are unfavorable for available light photography. There are various methods in which a single flash can be used to produce high-quality professional photographs that distinguish you, the Photographer's Mate, from the amateur snapshooter.

On Camera Flash

A commonly used flash technique is to have the flash unit attached to the camera in synchronization with the shutter and aimed directly at a subject. An advantage of having your flash unit attached to the camera is it provides you the chance to capture the unexpected—the truly candid shot. When spontaneity sparks the action and quick-camera handling is a must, the fewer pieces of equipment you have to worry about or handle the better. Rather than two pieces of gear—the camera and

the flash—you have only one—the camera with the flash attached to it; however, this technique usually produces objectionable shadows behind the subject.

To help reduce the harshness of the shadows produced behind your subject when a single flash is used at the camera, place some diffusion material, such as a white handkerchief, cheesecloth, or frosted cellulose acetate, in front of the flash. Of course, diffusion reduces the intensity of the light, and the exposure has to be increased accordingly when using the manual mode on the flash unit.

Most imaging facilities are equipped with flash brackets. When you are using a flash bracket, it is possible to rotate the flash when changing formats from horizontal to vertical. When shooting people in the vertical format using a flash unit, always position the flash above the lens. If the flash is below the lens, long objectionable shadows are cast behind the subject, and the subject has an unnatural, eerie, sinister effect.

Red Eye

A result that may appear with direct flash is “red eye.” Red eye occurs in pictures of people and animals when the flash is used close to the optical axis of the lens and the subject is looking at the camera. Light reflecting from the blood vessels at the back of the eye causes this effect. The darker the room is, the stronger the effect, because the pupils of the eyes become more dilated. Red eye can easily be avoided by moving the flash away from the lens optical axis. Also, the effects of red eye can be minimized by turning up the room lights.

Bounce Flash

One of the better methods to illuminate a subject or scene with a single-flash unit is to use *bounce flash*. There are times when you want a very soft light in order to lessen the tonal range between highlights and shadows and to soften harsh background shadows. You can achieve this soft lighting by bouncing, or reflecting, the flash off a light-colored surface. By doing so, you are changing the narrow spot of light from a flash unit into a wide diffused area of light. When shooting color film, avoid colored walls and ceilings. They reflect their color onto the subject, causing a color cast over the entire subject area. You should use bounce flash in all

DIRECT FLASH

DIFFUSED FLASH

BOUNCE FLASH

Figure 5-27.—Effects of direct, diffused and bounce flash.

situations where there is a 8- to 10-foot-white ceiling. Your photographs of reenlistments, frockings, awards, and so forth, will have a more pleasing effect.

Most bounce flash pictures are made with the light directed at the ceiling, either above the photographer or above the subject, or somewhere between. A silhouette effect can be produced by bouncing your flash off the ceiling behind the subject. To accomplish this, aim your flash unit so most of the light bounced off the ceiling falls on the background behind the subject and calculate the exposure for the background.

For the flattest bounce light, try bouncing the light off a wall behind the camera. With this lighting, you will have practically no shadows. Here, you have to calculate your exposure based on the flash-to-wall-to-subject distance.

For side lighting, bounce your flash off a wall to the side of your subject. This type of lighting helps add a feeling of three dimensions to your picture.

For the best control, use a large reflector designed for bounce lighting. Special-made reflectors are available that are lightweight, compact, and portable. For closeup work, the best bounce reflector is about 3 by 4 feet square. For full-length subjects, try a reflector about 6 by 6 feet.

To determine the exposure for bounce flash using the manual mode on your flash, you must determine the flash-to-ceiling-to-subject distance and determine your

f/stop and then open the aperture two additional f/stops. The two additional f/stops are added to compensate for loss of light due to scattering and absorption by the reflecting surface.

When an automatic flash is used in the automatic mode, it is not necessary to open up two f/stops. The sensor automatically cuts off when the proper amount of light is reflected from the subject to the flash unit.

When the ceiling is high or dark, a compensation to the basic exposure may be required. For effective use of the bounce-flash technique, a considerable amount of practice is required. As with any flash photography technique, identify any areas or surfaces that may be potential problems. Remember, one of the basic principles of reflected light is that the angle of incidence is equal to the angle of reflectance. Highly polished or glass surfaces should be considered before the subject is photographed. Items, such as windows, glass tabletops, glass framed photographs and polished metal, can cause glare or a "hot spot" in your photograph. When you are using bounce lighting techniques, "hot spots" of vertical surfaces are normally prevented, because the light source striking the surface is angled from above or the side; however, when you are using bounce lighting techniques, horizontal surfaces, such as glass coffee tables and overhead light fixtures, can cause a strange diffused lighting pattern in the photograph.

When using a single, on-camera flash, experiment with direct, diffused, and bounce-flash techniques and

determine which method provides the best results under various conditions. The method you choose to light the same subject separates you from the average snapshot shooter (fig. 5-27).

Off Camera Flash

Some of your best flash pictures can be made with the flash unit off the camera. Holding the flash off the camera and above the lens tends to throw the shadows down and behind the subject. This is a good way to minimize distracting background shadows that occur when a subject is standing close to a wall. A flash held high above the lens, either left or right, makes the viewer less conscious of the flash illumination. People are accustomed to seeing things lit from above, and by placing the flash above the subject, it closely resembles the lighting of the sun or ceiling lights.

Light that is far enough off the camera to illuminate the subject from an angle produces modeling or roundness. This type of light creates the illusion of a third dimension—depth—and is more pleasing to the viewer than the two-dimensional flat effect you get with direct, front lighting. Light from an angle can also be used to bring out the texture of a subject.

Indoors, two factors are important when determining the modeling and texture effects you will get: first, the surface of the subject itself; second, the way you light that subject. To illustrate these points, try photographing a Ping-Pong ball and a tennis ball together. When you use direct, front lighting, your picture records a two-dimensional visualization of height and width, but little of roundness, depth, or texture. When you light the balls from the side, both acquire the illusion of depth; however, only the tennis ball reveals texture. The Ping-Pong ball is much smoother and is almost textureless.

Now substitute a young child and an old person for the balls. With frontlighting, most of the lines and wrinkles in the old person's face will be minimized by the evenness of the light; however, when lighted from the side, almost every crease will become a shaded area and the ridges will be highlighted. Thus the texture of the old person's face is emphasized. The child, on the other hand, when side lighted, is still almost textureless just as in the case of the Ping-Pong ball.

LIGHTING RATIO

Lighting ratio can be considered as a measure of contrast. Lighting ratio refers to the combined intensity (at the subject) of the main and fill lights as compared

to the intensity of the fill light alone; for example, both the main and fill light of equal intensity are shining on the subject. A reflected light meter reading is taken off an 18-percent gray card at the subject position that indicates there are 100 units of light falling on the subject. Now, with the main light turned off and the fill-in light still illuminating the subject, the reflected meter reading indicates there are only 50 units of light falling on the subject; therefore the lighting ratio is 2 to 1. Lighting ratio is usually expressed as the comparison of two light intensities, such as 1:1, 2:1, 3:1, and so on.

The largest number in a lighting ratio indicates the most intense illumination at the subject position; for example, a 2:1 ratio indicates the most intensely lighted portion of the subject (highlights) is receiving twice the amount of illumination as the least intensely lighted portion of the subject (shadows). The light that produces the most intense illumination is called the main, key, or *modeling* light. The light that produces the least intense illumination is called the fill, or fill-in. A fill or fill-in light, as the name implies, fills in and softens the shadows produced by the main light.

Because a lighting ratio is a comparison of the combined main and “fill light” illumination intensities to the fill light illumination intensity alone, the fill light must be in a position so it completely illuminates the portion of the subject visible to the camera. This requires positioning the fill light close to the lens.

As a rule, 3:1 lighting is considered the best general lighting ratio for both black-and-white and color photography. This 3:1 ratio provides normal contrast between the highlights and shadows and produces good natural-looking photographs.

Some automatic electronic flashes allow you to control the output of light. When set in the manual position, you can adjust the light output by changing the intensity of the flash unit to 1/2, 1/4, 1/8, 1/16, and so forth. This allows you more control of flash-to-subject distance as well as aperture (depth of field) control.

Achieving the desired lighting ratio with an automatic flash unit where the flash intensity can be controlled is quite easy. To achieve a 2:1 ratio, you set both flash units at the same distance and at the same intensity (either full power, 1/2, 1/4, and so on). To achieve a 3:1 ratio, set both flash units at the same distance and set the main light flash at full power and the fill flash at one-half power. A 5:1 or even higher lighting ratio can be obtained by setting both flash units at the same distance and the main flash at full power and the fill flash at one-fourth power, and so on. In order to

select a wider aperture to control depth of field, start by setting your main flash at one-half or one-fourth power and adjust your fill flash appropriately.

Adjusting lighting ratios by flash-to-subject-distance is another method to control lighting ratios. An easy way to calculate footage for a 3:1 ratio with two lights of equal intensity is to think of the full f/stops (2, 2.8, 4, 5.6, 8, 11, 16, 22, etc.) as distances in feet. Place the main light at the desired distance closest to one of the "f/stops," and place the fill light at the distance indicated by the next larger number; that is, 5.6 feet and 8 feet or 16 feet and 22 feet, and so on.

Another easy method to control the lighting ratios using an automatic electronic flash is to use the flash unit in the automatic mode. When set in the automatic mode, the flash-to-subject distance is not supercritical, and there is some leeway as long as the flash units are within their operating range.

To obtain a 2:1 lighting ratio, you simply have both flash units set at the same automatic setting and at approximately the same distance from the subject. For a 3:1 lighting ratio, use the same automatic setting and approximately the same flash-to-subject distances, but set the fill flash at twice the film speed as the film being used (main flash setting). For a 5:1 or even higher lighting ratio, use the same automatic setting and approximately the same flash-to-subject distance and set the fill flash at four times more than that of the main flash, and so on.

Any lighting ratio can be obtained when using an automatic flash unit. By controlling the power output intensity, adjusting the film speed setting, changing the main and fill flash distances, or a combination of the three, you can manipulate the lighting ratio easily to any ratio. As with any stage of photography, practice and testing with your camera and flash combinations in various situations produces the best results.

SYNCHRO-SUNLIGHT

Bright sunlight, used as the only means of illumination for an exposure, can produce deep objectional shadows on a subject. When a flash unit is used as a fill-in source of illumination, it reduces these shadows and is known as synchro-sunlight photography.

Improperly handled, the synchro-sunlight technique can produce an effect that makes the photograph appear as if taken at night with a single flash. This effect occurs when the flash illumination is more intense than the sunlight.

The first step for proper exposure with synchro-sunlight is to calculate the correct exposure for daylight, and set the shutter speed and f/stop as though a flash is not being used; however, keep in mind when using a focal-plane shutter, the shutter speed must be synchronized with the electronic flash unit. Avoid using a fast film in bright sunlight when using a camera equipped with a focal-plane shutter. In this case, you are limited only to your aperture to control the exposure of the film, because your shutter speed is nonadjustable. A leaf shutter has an advantage over a focal-plane shutter. When a leaf shutter is used, it provides more control over depth of field since the shutter synchronizes at all shutter speeds.

When you are using an automatic flash, the same principles apply for synchro-sun that were explained in the section for lighting ratio. The sun is used as the main light, and your camera settings are determined directly from your light meter. The easiest method is to set the film speed (ISO) on your flash unit to twice the film speed being used for a 3:1 lighting ratio and four times the film speed being used for a 5:1 ratio. A fraction of the manual power output can also be used to achieve the desired lighting ratio.

Remember to compensate your exposure by opening up two f/stops for a backlit subject and one f/stop for a subject that is sidelighted when taking your light meter reading from a distance. For color photography, you should normally use a 2:1 or 3:1 lighting ratio. For black-and-white photography, a ratio of 3:1 to 5:1 is acceptable.

MULTIPLE-FLASH UNITS

Multiple flash is the use of two or more flash units fired in synchronization with the camera shutter. The flash units can be auxiliary flash units, connected to the camera by extension cords, or they can be slave flash units. Slave units usually have self-contained power sources and are fired with a photoelectric cell when light from a master flash unit strikes the cell of the slave unit.

With multiple flash, exposure calculations are based on the distance between the subject and the flash unit that produces the most intense illumination to the subject; therefore, you can have numerous auxiliary flash units or slaves for a scene and only calculate your exposure from the mainlight source. All other flash units should be equidistant or at a greater distance from the subject as compared to the flash unit on which the exposure is based.

When two flash units of equal intensity and at equal distance from a subject illuminate the same area, the exposure for one unit should be determined and then the exposure should be halved because twice the intensity of light is reflected from the subject.

OPEN FLASH

Flash pictures can be made without the camera shutter and flash being synchronized, using a technique called open flash. In the open-flash method, the camera shutter is set at T or B, the shutter is opened, the flash unit fired, and the shutter closed. The open-flash technique is sometimes used when the level of light over a large scene is very low or at night. This method of flash photography allows the photographing of large scenes that ordinarily are quite difficult to illuminate with artificial light. The photographer can walk into a scene with the flash unit and illuminate sections of the scene or the entire scene. Any number of flashes can be used during the exposure while the shutter remains open. A silhouette of your body can be recorded if your body gets between the flash and the camera.

To arrive at the exposure for an open-flash picture using a manual flash, determine your flash-to-subject distance and f/stop. Keep the distance equal to the objects being illuminated when using manual flash; for example, when the f/stop for the scene is f/5.6 based on a flash-to-subject distance of 10-feet, every flash within the scene should be 10 feet from that section of the scene being illuminated. When an automatic flash is used, the flash automatically shuts off when the proper amount of light is reflected from the subject, providing the object is within its distance range. When you are using a manual flash, the exposure for open flash is determined as previously discussed. This is true unless two or more flash units with equal intensities are used at equal distances, or two or more flashes from the same unit at the same distance are used to illuminate the subject.

MULTIPLE EXPOSURES WITH ELECTRONIC FLASH

Interesting multiple exposures can be made with only one or two electronic flash units. Multiple exposure pictures, besides being artistic and interesting, are often used to study subject motion and position. This can be accomplished by the following procedures:

1. Darken the room and position your subject against a black background.

2. Allow enough background area for the number of different exposures you intend to make. When you

are using a ground glass camera, mark off on the glass, with grease pencil, the areas where the subject should be for each different exposure. If not using a ground glass camera, make a pencil sketch to help you position the subject.

3. Set up the electronic flash lights so the minimum amount of illumination falls on the background itself.

4. Turn off all room lights and make your first exposure. Then, without advancing the film, move your subject to the next position for the second exposure. Repeat this procedure for each image you want to record on the film.

PHOTOGRAPHING ACTION WITH ELECTRONIC FLASH

Action of any kind, no matter how slight, can add interest to most pictures. Each type of action requires a different camera technique, but because of the short duration of light from electronic flash, it is ideal for recording any action ranging from a fleeting expression to a sports triumph. Most electronic flash units have a maximum flash duration (the length of time the light is on) of about 1/800th second, and a minimum flash duration as short as 1/20000th second, thus you can “freeze” almost any action with the flash.

Indoors, where there is little existing light, you have no problem because the electronic flash itself stops the action; however, outdoors in daylight, you may encounter ghost images. Ghost images can occur when existing light and a slow shutter speed are used in conjunction with electronic flash. A ghost image appears as a blur when one image is recorded by the existing light and a second sharp image by the electronic flash.

ELECTRONIC FLASH AT NIGHT

Flash photography, outdoors at night, can produce very underexposed photographs if not taken properly. Outdoors, flash does not carry very far; therefore, it can be difficult to light objects from a distance; however, this limited coverage also gives you great control. Indoors, part of the output of a flash unit is reflected from the ceiling and walls back to the subject. Rarely do you find such reflective surfaces outside, so some light is lost. To compensate for the light lost, you must open up your aperture when photographing objects at any distance. Because so much light is absorbed in these large areas, it may not be uncommon to open up your aperture two or three f/stops. Tests should be conducted before shooting in large, indoor areas, such as gymnasiums and hangar bays or outdoors at night, to

determine which flash, camera, and film combination produces optimum results.

At night a single on-camera flash produces stark lighting, and your subject is flatly lit and the background goes completely black. Close foreground details become very overexposed, and it is better to exclude them. Such simple lighting is ideal for action shots; for example, capturing leaping karate experts in midair at midnight. Subjects such as these benefit by being isolated from the background, but you may get more interesting lighting by using the unit off camera on an extension cord.

If the necessary flash-to-camera distance is greater than the length of your extension cord, use the open-flash method. Do not allow the camera to “see” the flash unit during the open-flash exposures.

Now that you have a basic knowledge of photographic techniques, it is important that you apply and practice the basic principles. Each and every time you pick up a magazine, book, or newspaper or watch TV or see a movie, you are exposed to various composition and lighting techniques. Study them and apply them every time you look through the viewfinder of a camera. Remember, experiment with different camera angles to create interesting perspectives of your center of interest. Whether using available light or flash photography, notice what results the direction, intensity, and type of light have on your final product. Continual application and refinement of the principles of composition and lighting can greatly enhance the quality and aesthetic value of your photography.

CHAPTER 6

PHOTOGRAPHIC ASSIGNMENTS

Photography in the Navy has long been an important tool for monitoring the strength and improving the methods of our nation's fighting forces, as well as serving to record for historical permanence the significant events that have shaped our nation's destiny. From the moment that Matthew Brady exposed his photographic plates on the decks of the federal ironclad ship, *Monitor*, in 1862, the Navy has used photography as a significant recording medium. It has influenced the development of weapons and ships in the Navy and has been an invaluable aid in training the men and women who make up today's Navy.

Today we can go to the archives and look back with pride at the visual evidence of the Navy's growth, generation after generation. The historical record tells us where we have been, what we were, how far we have progressed, and how we have changed-enhancing our perspective of the past and clarifying our perception of the future.

The "grandfather" of our profession, still photography, is the oldest of photographic skills in the Navy. Where events of historical significance occur, such as military exercises, ships being commissioned and decommissioned, and newsworthy events of interest to Navy personnel, there are Navy photographers recording events as they happen.

PLANNING

Planning prevents disappointment. If only I had an idea of what to expect, this picture might have been better. How many times have you said this to yourself? Planning does not cover all the bases on every assignment, but it can be valuable on many of them.

Color or black and white . . . small, medium, or large format? This question may sound basic, but you should consider it thoroughly when preparing for an assignment. Take time to consider the finished product and its intended use.

Punctuality is the only policy. As a minimum, be on time. However, why not get there 10 or 15 minutes ahead of the assigned time? You can use this time to look over the area for lighting, background, props, and so forth. Also, discuss the assignment and what you need with the people connected with them. Take charge

courteously. Politely ignore harassers. Begin work at once and give clear, concise directions. But do not think this approach takes the place of your responsibility to BE COURTEOUS AT ALL TIMES.

Dependability versus creativity. Strive to shoot for the results that your customer requested. Then shoot what you consider to be an improvement on the original requirement.

Pictorial details are important. Before the shutter catches that moment, make sure you have checked or considered the foreground, background, arrangement, expressions, clothing, angle, and lighting. You have to mentally put all these items together and say to yourself, Will this tell the story?

Identify. When the photograph has been recorded, begin taking identification Caption information should include name, grade, and title. If possible, you might have someone on the scene taking identification while you are shooting.

Always check your equipment before leaving for a shooting assignment. As a minimum, you should take several extra rolls of film and a spare synchronization (sync) cord. When using a flash and a large number of photographs are to be taken, you may need an extra battery pack. Always be prepared and attempt to overcome the unexpected.

EQUIPMENT

After learning the nature of your photographic assignment and making a complete analysis of the assignment, you must choose the proper equipment to get the job done. The variety of photographic equipment available and suited for location assignments is extremely broad; for example, the assignment may require the use of a 35mm, medium format, or even a 4x5 view camera. The lighting equipment you choose may range from a small, compact electronic flash unit to a complex array of lighting equipment and reflectors. Exposure meters, color temperature meters, tripods, and interchangeable lenses are just a few of the other accessories you may need on a location assignment.

"Be prepared." At one time or another we have all heard that familiar quotation. But have you ever thought what this could mean to your assignment? For want of

a gizmo, a photograph was lost; for want of a photograph, an assignment was ruined; and for want of an assignment, your reputation as a photographer was destroyed. No, we are not really concerned with gizmos here. What we are concerned with is your equipment. Do you have everything you need when you get to your assignment and does it work? Nearly all photographic equipment has one or more critical components-the failure or loss of which may put a vital piece of gear out of operation. With cameras, one of these items is the battery, because it may power both the meter and the shutter. Check the battery before you leave the lab, and ALWAYS carry a spare. You have a super deluxe all-powerful electronic flash unit that can light up the entire hangar deck in the wink of an eye. Or can it? Did you check it out and was it working before you left the work center? Did you remember the power cord and an extra sync cord? Speaking of synchronization, did you make sure the flash was in sync with the camera shutter? Or was the shutter even working? What about the camera lens-is it clean, does it focus correctly? The diaphragm-is it working?

In the studio, a minor failure usually only causes embarrassment and gives the impression of unprofessionalism. You can usually get a spare camera, lights, and tripod into service. But when you are out on location, you are limited in what you can take with you; therefore, it is important that ALL your equipment be thoroughly tested and operating correctly BEFORE you leave the work center.

MARKING YOUR EQUIPMENT

If you have been issued your "own" equipment, put your name on it. Of course, you should not put your name on it permanently. Use stick-on labels. Having your name on your equipment does not keep anyone from stealing it; it is only there to let other people in the workcenter know it is "yours" **and they best keep their hands off.** Navy photo equipment must be marked permanently with both a serial number and "U.S. Navy Property." If the manufacturer did not include a serial number on the equipment, a local serial number is assigned, using the unit identification code (UIC) under which the equipment is assigned, plus a dash and a two or three-digit number that identifies the specific piece of equipment; for example, if you receive a new light meter without a manufacturer's serial number, your work center UIC is 62093, and you have 76 other pieces of equipment assigned local serial numbers, then the serial number for the new meter is 62093-077.

EQUIPMENT SECURITY

In the photo lab, your equipment should be secured when not in use. Most imaging facilities have a camera-crew ready room or locker that is kept locked so only authorized personnel have access to valuable photo equipment. On location, however, security is another matter, particularly when away from your home station. There may be times when you must leave equipment in a BEQ or motel room. There are measures you can take to protect this equipment. The first principle is do not advertise your equipment. Do not put anything on the equipment cases to indicate they contain photographic equipment. Do, however, put your command address on the cases. The second principle is not to leave photo gear out of your sight any longer than necessary. Carrying a camera bag with you to chow may be inconvenient-but this is better than leaving it unattended somewhere. Also, do not leave your photo gear in a location where it could easily be picked up or stolen. Keep a strap attached to the bag or case, and drape it over your knee.

PHOTOGRAPHING PEOPLE

People are probably one of the most rewarding subjects for photography. Good pictures of people capture the gestures and expressions that convey vitality and character without the subject appearing self-conscious.

Basically, assignments for photographing people fall into two general categories: pictures of a single person and pictures of a group of people.

For the mediocre photographer, all the picture of a person must do is identify a person. But good photographers steer away from these identification pictures. The photographer is after something different, something not too loose and not too formal-something that pictures the person, not just his features. One approach to capture these characteristics is the candid photograph.

CANDID PHOTOGRAPHY

Most photographers are familiar with candid shots of people they do not know. It may be true that the average photographer thinks of a candid photograph as one that is not set up or one the subject does not know is being taken. Photographers have learned that candid techniques can be used just as effectively to make pictures of people they know, even when the people know they are being photographed. The key to success as a candid photographer is to keep a low profile, but you do not have to be sneaky. A candid shot is a candid shot, whether it is of the admiral at a news conference

or a “genuine candid” of a sailor you just happen to see. The technique is the same in both cases. All that is important is for the pictures not to appear posed. The subjects of candid photographs are not posing or acting; they are simply being themselves and behaving as though the photographer is not there.

The compactness of 35mm cameras make them ideal for candid photography. SLRs with their fast, interchangeable lenses, TTL metering, and large film capacities make candid photography one of the most rewarding areas of our profession. A long-focal-length lens is also a good choice for this type of photography. The long lens lets you maintain distance between yourself and the subject, and, if people are aware of your presence, they will not be as self-conscious. If you are taking “real” candid shots, a long lens is a necessity.

When people know you are shooting them, get them to occupy themselves, so they will “forget” there is a camera watching them. Only then, can you get a truly candid picture. When the person notices what you are doing, ask their permission before you shoot. People usually will not object, particularly if you are polite and work quickly. Stay casual and relaxed. People soon get used to seeing you with the camera, and you will be on your way to some good candid pictures.

Preset your focus and exposure whenever possible so you can respond quickly and avoid attracting attention to the camera. Estimate the likely subject distance, set it on the lens focus scale, and stop down for greater depth of field. Camera handling must be fast and smooth. Time does not allow for fumbling with camera controls, flash equipment, exposure meters, and film loading.

Keep alert, keep looking, and keep shooting. Shoot plenty of film. Do not be stingy; in the long run, film is cheap. You will miss enough good pictures by the very nature of your subjects-people-and being tight-fisted with film does not increase your chances for getting good pictures.

Do not try to control the people you are shooting. Let them assume a natural “pose” in an appropriate setting. You may tell them, “please do not look at the camera.” Try to capture the details of their environment in your pictures. This adds interest to what they are doing. And finally, make your candid pictures reflect the people and events around you.

There are situations when you do not have the time for a candid approach, or it just is not feasible. You can still produce interesting people pictures by using the “frame approach.”

FRAMING PEOPLE IN THEIR ENVIRONMENT

The “frame approach” simply means posing your subject in a situation or environment that is most meaningful to the subject or assignment.

When your subject is a chaplain, place him before a chapel or at a desk with a cross that is visible over his shoulder. If the person is a Boatswain Mate, get him or her on deck actually working on the job. Put the Navy instructor near a blackboard or the pilot in an aircraft. The frame approach works with people working in all types of environments and ratings, such as Machinist's Mates, Airman, Fireman, Personnelman, Opticalman, and so forth. It works with just about everybody. It is easy. Your subject is usually more relaxed in his or her own environment, and props to work with are already there.

Before you approach an assignment, have the one key ingredient to success in mind-**a definite idea of what you want**. In other words, plan ahead. Find out all you can beforehand about the subject and the environment. What could be worse than arriving at an assignment and finding your “just average” Personnelman is really six-foot-four, completely bald, and wearing thick bifocals. It might help to know that even though you find the person in a “closet” called an office, most of the work is done in the computer room down the hall-the one with the banks of computers and tape racks that make wonderful “frames.”

There are some things you must remember. Use the frame approach to maximum advantage. The first and foremost is to **exaggerate**. Be sure to really have a frame for your subject. If your subject is a legal officer, make sure there is no mistaking that this person works in the courts or with books and papers. If your chemist is at a blackboard, make sure that there is something on it and that the test tubes are not hidden or too few. Again, **exaggerate**. You are going from three dimensions to two. Do not be subtle. Your objective is to make a meaningful picture of a person, not just an identification shot. Vary your setup-get in tighter-back off some-change camera angles-and keep the subject prominent.

The overall result of your efforts should be a unique picture. Even if you were unable to capture the personality of your subject, the picture should at least be personable. This can be done by making the person a prominent part of the picture. Photograph the person in a meaningful environment, one that gives a sense of who the subject is, and what he does, rather than leaving the viewer with a sense of only what he looks like.

The objects needed to frame your subject must be associated with the person. You would not want to frame a Seabee with the wings of an airplane (unless of course a runway is being constructed). The Seabee would be better framed by the arch of a new building being constructed, or the hood and engine of a dump truck. The frame should add emphasis and lead the viewer to the subject. **Do not make the frame the subject.** The frame does not always have to be in focus or "box" the subject. Study pictures of people that have been framed. Sometimes the frame is only on one side of the subject, sometimes in back of the subject, and sometimes only in the foreground. Seldom does the frame completely box the subject.

PEOPLE WORKING

When you read an article about someone, it may be accompanied by a picture of the person who is often at work. A picture of someone at work says more to a viewer than an ordinary head-and-shoulders identification ever can, because it immediately places the person in a particular setting.

The secret to making good working pictures is to capture the atmosphere of the **place** and show the **subject** actually **working**. The use of a wide-angle lens lets you show a large work area from close in. This conveys a better idea of the working conditions. Try to bring out the atmosphere of the worker and the workplace; for example, if your subject does hard manual labor, try a low camera angle to create an impression of power. Although it is usually better to photograph a worker as though he were unaware of your presence, this is not always possible. Warn people when you are going to use the flash, so you do not startle them. When shooting at a slow shutter speed, you can even ask the worker to hold a pose.

Most people who are working are involved with something that can provide a prop: books, scale models, equipment, and so forth. Use these props to create a stage and put the people into it—really into it.

TWO-SHOTS

So far, the discussion has been based on shooting pictures of only one person. Another assignment facing the photographer is handling the two-shot, a picture showing two people.

People can be pretty awkward when told to "just be natural" or "just talk to each other." It is better to give them something to talk about. Have them talk about what they are doing. Tell them you are listening to what they say so you can have information with which to write your captions. Better yet, give them something

they can actually handle, talk about, and concentrate on. This makes the situation more realistic to them, and it results in better quality pictures.

Try the frame approach for your two-shots. It is very effective. Even people can be used to frame other people.

DIRECTING PEOPLE

One of the most difficult tasks in photographing people is directing them. But you, the photographer, are the only one that can actually see what the picture is going to look like before it is taken. So, you must take the responsibility for setting up the "pose." It is not enough to let your subjects just arrange themselves. They have no idea what they look like.

One way to make directing and posing easier is to give your subject something to do. Do not tell your subject to "just stand there," as though in a vacuum, with nothing to do. Instead, give your subject something to handle. For a man, it might be a pipe, a book, a spyglass, or a tool they use in their work. For a child, it could be a doll, a model plane, or something of a similar nature. Often a woman can use an item of clothing in this way—a hat or a scarf.

Another useful tip is to give your subject a "prop" or a support in a more literal sense—something to lean on or sit on. A chair, stool, post, or tree can be used. When using props, frames, and poses, do not forget one important point: The Navy uses photographers so its pictures are made by professionals. These are people who know what they are photographing and the reason why. A civilian photographer could most probably make an excellent picture of a Navy scene; however, it probably will show technical errors that make the picture look like a joke to other sailors. Do a little research. If using props that you do not understand, ask about them. Do not have a sailor hauling on a line that should be taken to a capstan or a Gunner's Mate holding a 3-inch shell in front of a 5-inch gun.

Eyes are very important when photographing people. You must direct the subject to ensure that all parts of the scene are in the right place or in proper perspective. You must also direct the expression of the subject. The eyes are a very vital part of this and have a significant effect on the viewer's response. In a picture where the eyes of the subject are looking straight into the camera, a strong and immediate impact is created. This attracts viewer interest. When the eyes are directed away from the camera, the effect is less explicit and has a more ambiguous quality.

Finally, you must be in charge of the situation. It is up to you to tell the subjects where to stand, what to do, how to do it, and when to do it. This applies to everyone.

PHC Chet King

Figure 6-1A.—LT(jg) Robin T. Russler stands watch on the flag bridge of the USS *Tripoli*.

Do not fear the brass. They need directing too; after all, you are the professional and that is why they “hired” you—to do your job and to produce the best possible pictures of them. Many people are nervous and self-conscious in front of a camera. They try to look their best, and in so doing often present an expression or pose that is unnatural and displeasing. You are obligated to provide directions to the subjects regarding their pose. As the photographer, it is your responsibility to ensure

that coat sleeves are pulled down, wrinkles smoothed out, hat set at the proper angle, body erect, head tilted at the best angle, and a dozen other things which, if not corrected, detract from the picture. Whether the subject is a seaman or an admiral, the photographer must observe these discrepancies and correct them. Figure 6-1A and figure 6-1B present examples of pictures of people in their environment.

J01 Joe Lancaster
302.273

Figure 6-1B.—A member of the Army's 7th Infantry Division takes a break during the combined South Korean and U.S. exercise *Team Spirit 1990*.

One of the greatest contributing factors to poor pictures is the timid manner in which a novice photographer handles the subject. Never take a picture when something is wrong because you are afraid to speak and act in the presence of high-ranking personnel. The results will surely be disappointing and embarrassing; however, you should always be courteous and respectful in dealing with your subjects regardless of rank or rate.

GROUP PICTURES

Occasionally, assignments are received to take a picture of a group of people. There is added difficulty when working with a number of people at one time. Each person should be treated as an individual, and, at the same time, each person's relationship to the whole group must be considered. Attention must be paid to every member of the group. Every precaution should be taken

PH3 Borbely
302.274

Figure 6-2.—Boat crews aboard the USS *Theodore Roosevelt* pose with their motor launches.

to ensure that each person is shown clearly and that interest is not drawn to one individual by some awkward pose or expression.

There are two general types of group pictures: formal and informal.

The formal group picture is one in which several people, uniformly dressed for the occasion, are seated

or standing in as nearly the same pose as possible. Each member is placed in approximately the same relative position so that attention is not drawn to one person.

The informal group picture (fig. 6-2) is intended to depict an action or tell a story about the individuals concerned. Although the position and pose of each member of an informal group is carefully planned, the

results must appear casual and realistic. The members may be seated, kneeling, or standing in a variety of positions and do not have to be looking in the same direction.

Arrangement of personnel to obtain the best composition is one of the most important factors in group photography. Regardless of the number of persons in a group, they should be arranged to fill the picture in such a way so you get the largest possible image size of each person. One exception to this general rule is when the importance of the background is equal to or greater than the group itself. This often occurs with an informal group when the picture is actually intended to emphasize an object or piece of equipment, rather than the individuals. In this case, locate the camera for the best composition of the object; then arrange the people in the picture to enhance the story being told

A formal group of about five people can be composed to fill the picture area very nicely. When six to ten persons are being photographed in a group, it is advisable to arrange them in two rows. For larger formal groups, arrange the people in as many rows as necessary to fill the frame. Avoid stringing out one long, narrow line of people across the frame.

When a large group is formed into three or more rows, you must devise some method to prevent the rear rows from being blocked from view. Furthermore, in order to compose the picture properly and fill it from top to bottom, you must see that each row is higher than the preceding one. One method is to arrange the group on the steps of a building, bleachers, or a terrace, so each row is higher than the preceding one. On level ground the first row can be seated, the second standing, and the third standing on benches. Another method that can be used in combination with the first is to elevate the camera so it is pointing down at an angle on the group. This method is useful as an aid in composing and filling the picture area. A higher camera angle can be useful in eliminating an undesirable background. When raising the camera above eye level, you must avoid excessive distortion of the figures and vertical lines by too much elevation.

Particularly in formal group photography, the arrangement should be symmetrical. But avoid having an equal number of persons in each row. Keeping the number unequal permits each person in the second and succeeding rows to stand directly behind the space between the heads in the preceding row. This provides a much better view of each person. The number in each row should differ by one person.

Figure 6-3.—Arrange long rows in a semicircle.

Customarily, in a formal group, the highest ranking person is located in the center of the first row and other members of the group are arranged alternately to the right and left by grade. When all members of the group are the same grade, arrange them according to height, with the tall ones either in the center or at the ends, or occupying the rear row.

When you are arranging a large group in which about twelve or more persons are in each row, it is advisable to form them in a slight semicircle instead of a straight line (fig. 6-3). This places each person approximately the same distance from the camera and keeps the images a uniform size. Instruct each person to turn slightly so he or she is facing directly toward the camera.

The shorter the focal length of the lens used, the more pronounced is the distortion effect of apparent bending of a straight row. A proportionally greater distance exists between the center and the ends of a row with a camera having a short-focal-length lens than with one having a long-focal-length lens.

When the formal group is arranged and ready to be photographed, ensure each member is in the same relative position, hats are at the same angle, and uniforms are correct and neat. See that the hands and

Figure 6-4.—Formal group photo.

302.275

feet of all members are in the same position. When the front row is seated, the feet may be crossed but all in the same direction. Each person should be looking at the camera, no broad smiles, just pleasant expressions. Nothing should be so different about one person that it draws an excessive amount of attention. Remember, to get maximum depth of field, you should focus the camera one third of the way into the group (if there are nine rows, focus the camera on the third row).

As with everything else there is a time and place for formal group shots. What would happen, though, if you “stylized” the shot just a bit? Instead of always shooting the group setup that clearly identifies each member in the typical “lineup” by grade or height, why not think of your group picture in terms of your other photographs? Put in some foreground or a background. Use an interesting bit of lighting or a somewhat different setting. After all, do your subjects really have to be shoulder-to-shoulder? Do not forget the frame approach; it can work for group shots too. The group can be placed in a situation that has some relation to it. Foreground objects can be used to create a frame for a group of people in a photograph. Even one of the group members—the squadron commanding officer—can be your foreground; the rest of the officers can be scattered throughout the background.

The success of a formal group photograph (fig. 6-4) is dependent on your ability, as a photographer, to direct the members of the group so you can obtain the

composition desired. Never hesitate because of grade to request members of the group to change their expression or position or to correct a discrepancy in their uniform. Be diplomatic about it, of course, but do not let the matter go unattended. It is embarrassing and a waste of valuable time to call a group together again to retake a picture regardless of the reason for failure.

The most important lesson a novice photographer can learn about photographing groups is how to remain in charge. Unless you are very careful the group will take control, and getting all the members of the group to look at the camera at the same time becomes almost impossible. Unless you are the dominating type, maintaining control is not easy. Remember, you cannot make good group pictures unless you are in control of the situation. To be in control, you should keep talking to members of the group and monitor their behavior. Have your equipment ready so you do not waste time or lose the group's attention while you load film or reposition the camera and lights. When you talk to people, they will naturally look at you, and therefore at the camera. Your directions and “patter” also prevent them from getting a word in edgewise among themselves. You must be firm when it comes to arranging the group. Do not be afraid of moving people about and telling them where to stand. Remember, you are making the pictures; you can see best what the final result will look like.

PEOPLE IN ACTION

When you photograph people in action, such as in sports and at work, the name of the game is anticipation, staying alert, and expecting the unexpected. Covering action events becomes an exercise in “guesstimating” where the action will take place and firing the shutter at the right moment.

A good action photographer relies on his knowledge of the event taking place; for example, if you will be photographing a General Quarters (GQ) drill and the principal players are going to be the Hull Maintenance Technicians, you could take a crash course in the job they will be performing during GQ. You might even observe them going through the drill a day or two before it is time to photograph them. Like a sports photographer-you must know the rules of the game. Even if you cannot learn the game, a photographer that understands the principles of shooting people in action can do a good job by following a few simple rules:

- Anticipate the action. Watch for the unexpected moment.
- Know the mechanical functions of your camera equipment. Practice aiming, focusing, and shooting until they become reflex actions. This leaves your mind free to concentrate on the event.
- Learn something about the action you plan to photograph.

The best pictures of people usually have action, implied or apparent. The action should be appropriate to the subject of the picture. The cook, for example, should not be shown in the boiler room (unless for a special reason or effect). Even a posed picture can have plenty of action and interest and not seem at all posed. Artificial, stiff effects kill the picture. Avoid static, dull pictures of groups staring directly into the camera. Plan and shoot for action, such as applause shots or a speaker making gestures, or shots of an audience's facial reactions. Break up the overall scene into small groups of action, such as shots of important persons talking, the guest of honor shaking hands with others, and so forth. Even an attitude or arrangement of hands, feet, head, and shoulders often creates action. There is action in everyday living, in working, eating, drinking, smiling, arguing, driving, flying, sailing, and swimming. It is not so easy to capture action in still photographs, but by understanding the importance of action in a picture and the abundance of action available everywhere, you will soon become proficient at recognizing and picturing it. The blur technique has become popular for advertising

and illustration use. Panning the camera with the action of a moving subject keeps the subject fairly sharp while blurring the background in a horizontal sweep, and this gives the feeling of action. A slow shutter speed is needed. Try the technique and see the interesting results.

A photo should have emotional mood and impact that can be accomplished by actual movement of a physical nature. The head may be raised in victory or joy or lowered in despair and sadness. The body sagging or the body squared away indicates different moods. Arms on the hips can indicate swagger, arrogance, or confidence. Hands in pockets indicate relaxation, or at the sides, may show formality. Knowing the elements of action, how to recognize them, and what moods they convey permits you to click the shutter at the right instant when you recognize outstanding action happening. The shooting angle, lighting, and composition all contribute to a feeling of action.

Action should always be photographed at its peak (fig. 6-5). This is a matter between the photographer and the photographer's own well-developed sense of motion. A highly capable photographer knows with certainty, at the instant he or she shoots, whether the picture will be a good one or not. This does not come from occasional picture taking but from steady, continual practice.

COMMAND FUNCTIONS

The majority of the job orders your imaging facility receives will probably be in support of providing photographic documentation for command functions. Photographic assignments that fall into this category are as follows: reenlistments, retirements, change of commands, awards presentations, and VIP (Very Important Person) visits. Some of the larger imaging facilities provide a photo mailer service whereby amateur photographers take snapshots of their command functions and forward the film to the imaging facility for processing. For those Photographer's Mates that are fortunate enough to cover these photographic assignments, high quality and professional service and products are imperative for the continued success of customer service and satisfaction.

To provide the best photographs possible, you must apply all of the principles and techniques discussed previously in this TRAMAN. Proper planning, composition, and lighting must be applied regardless of how routine you feel the job may be. Some general guidelines are as follows:

- Always use bounce flash whenever possible.

302.277

Figure 6-6.—Award presented by the former Secretary of Defense Frank C. Carlucci

- The reenlistee, retiree, or person being advanced, promoted, or receiving an award is always the subject (fig. 6-6). Regardless of who is presenting the award or conducting the ceremony (whether it be the division officer, commanding officer, or the Secretary of Defense), the recipient is always the center of interest.

- ◆ Avoid profile photographs of the subject. If necessary, shoot over the shoulder of the person presenting the award or conducting the ceremony.

- Prevent objects from giving the appearance of protruding from a person's head or body, such as pipes, flags, or doorframes. Always view the entire subject through the viewfinder and adjust your camera angle or viewpoint as necessary to prevent this compositional flaw.

- If you miss a shot or you know the photograph does not meet your standards, such as eyes closed, face hidden, or flash does not fire, always re-shoot the photograph. When it is not possible to re-shoot immediately, setup and re-shoot after the ceremony.

When in doubt, re-shoot. Film is relatively cheap, but your reputation and the reputation of the photo lab is not.

- Never fake a shot. If you run out of film or have camera problems, make arrangements to take photographs at a later time. Better planning and improved communication will normally prevent this from happening.

CAPTION WRITING

Photographs, despite their unique story-telling ability, are seldom effective enough to stand alone. No matter how exciting the picture may be, it fails unless the viewer understands the five Ws—Who, What, When, Where and Why of the photograph. The area of providing information that the photograph cannot give is in the caption—the text that accompanies the photograph. It is your responsibility, as the photographer, to gather the necessary information and write complete, concise, and factual captions.

The caption supplements the photograph by answering the five Ws. It provides clarification of important details that are not readily apparent in the photograph. To make a caption work, you must use three basic elements:

- An explanation of the subject
- Identification of persons or things in the picture
- Additional details of background information

In caption writing, the first sentence is the most important. It must describe the action without overemphasizing the obvious. Always use the active voice of the verb and write in the present tense. Another important consideration in caption writing is background information. This consists of additional facts or explanations needed to clarify the photo. The amount of background information included depends on where the picture will be located and how it will be used.

Whether the photo will be printed in a military or a civilian publication, used in a report, or used as a display picture is of primary importance. The caption explaining a picture of a sailor wearing an oxygen breathing apparatus to a civilian is more difficult than explaining it to another sailor.

The second consideration, how the photograph is to be used, refers to whether it will be used alone, as a single picture, or used in conjunction with something else, such as a news story or report. When the picture is to accompany a news story or a report, the caption should not repeat details used in the text. On the other hand, when the photograph is to be used as a single picture, it must tell the whole story, and the amount of background information must be enough to provide the reader with all the necessary details. In other words, the caption and picture combination must tell the complete story.

The answers to the five Ws should be given in vigorous, forceful language without sacrificing simplicity and brevity.

WHO—Give as much information as possible about the personnel shown in the photograph, beginning with paygrade, rate, or rank and full name.

WHAT—Used to identify ships, aircraft, awards, and other things shown in the photograph.

WHERE—Identifies the location of the event.

WHEN—The actual time or date of the event.

WHY—The reason for a particular operation or action taking place.

The novice caption writer is often confronted with the problem of how long to make the caption. Although there is no prescribed length for captions, the general rule is one paragraph, preferably in 50 words or less. Caption content is your last opportunity to tell what makes a photograph significant. The shorter you make the caption and still tell a complete story, the better.

There is no best way to write a caption. There are, however, rules that make caption writing easier. One proven method is to make use of the three basic elements: **explain the action, identify persons or things in the photograph, and give necessary background information.**

EXPLAIN THE ACTION

The first of the three elements, explain the action, is the most important part of the caption. The very first sentence must link the caption to the photograph by describing the action. One of the peculiarities of the first sentence in caption writing is its verb form. Since a photograph has “frozen” a moment in time, the verb should be written in present tense. This provides a sense of immediacy, as though the reader is actually witnessing the event. For example:

"Petty Officer Second Class Paul T. Boat swims through swirling flood waters of the St. Johns River to rescue 6-year-old Sammy Cameron"

This has more dramatic impact than a caption which reads:

"Petty Officer Second Class Jane B. Doe swam through"

There is, however, one problem that arises from the use of present tense in the first sentence. What to do with the “when” or time element? If the when or time element is included in the first sentence, the result reads something like this:

"Pete Rose hit a line drive to center field yesterday"

A sentence, such as this, would be somewhat jarring to the reader and should be avoided. To alleviate the problem, you should leave out the when or time element of the first sentence when writing captions, thus avoiding an awkward shift in tense.

IDENTIFICATION

The second element of caption writing, identification, frequently poses the question of who or what should be identified in the photograph. There is no magic formula to cover every situation, but the general guideline is to identify everyone or everything that is identifiable, and pertinent to the action. A pertinent individual or object is one that is involved in the central action of the photograph. In other words, anyone or anything in the photograph that attracts attention should be identified. Identification should come as early as possible in the caption. Many times you can identify people or things at the same time you describe the action.

"BM3 Jack R. Frost sounds taps to climax
Memorial Day ceremonies"

Here the action and the man are identified together. The only exception to placing names high in the caption is in the case of group identification. The recommended way to handle group photographs and still maintain reader interest is to use an impersonal identification in the first sentence; that is, "A group of sailors . . .," then list the names at the end of the caption. This method achieves complete identification without cluttering the all-important first sentence.

Identification in caption writing can be handled in any one of several ways. The idea is to handle it in the most natural and concise manner consistent with clarity. To ensure consistency, the caption writer generally uses four methods of identification:

- Action
- Obvious contrast
- Elimination
- From the left

Action is, of course, the best method. When a little league baseball player is sliding into second base, it should be obvious from the action which boy is the base runner; therefore, it is not necessary to say left or right as a means of identifying the players.

Obvious contrast is another simple way of identifying people in a photograph. If the commanding officer and an airman recruit are photographed, it is not necessary to identify the commanding officer as being left or right.

Identification by **elimination** is slightly more complex but nevertheless very effective. Suppose there are four people shown in a photograph. The

commanding officer of the photo school is presenting a citation to a third class petty officer. These two are identified by the action. A third person, the petty officer's wife, standing alongside, is identified by obvious contrast. The fourth person, the award recipient's division officer, is then identified by elimination.

The fourth and least desirable method of identification is **from the left**. This method of identification should be used only as a last resort or when there is a chance of confusion from using any of the other methods, such as in identifying groups of people. When you use this method of identification, it is not necessary to say, "From left to right." To do so only wastes space. Logic tells us that if we start from the left there is no place to go except to the right. The task is therefore simplified by saying, "From the left."

BACKGROUND INFORMATION

Background information is our third element of caption writing. It consists of additional facts or explanations needed to clarify the photograph. It is often impossible for the photograph and the five Ws alone to provide all the details necessary for a complete understanding of the photograph. Therefore, it becomes necessary to provide the viewer with additional information for the purpose of clarifying the photograph.

How much background information is needed to clarify a photograph depends on two factors: where the photograph is to be used and how it is to be used.

CREDIT LINE

The last part of caption writing is the **credit line**. The usual method is to credit both the photographer and the service. While there is not a set standard for giving credits, the following format can be used:

Official U. S. Navy Photo by:
PH2 Jack R. Frost, USN

Or the credit line can follow directly after the last word of the caption, as shown in the following example:

Line handlers cast off the stem line as the amphibious force flagship, USS *Eldorado* (AGC-11) gets under way for a Western Pacific deployment. (Official U. S. Navy Photo by: PH2 Jack R. Frost, USN.)

A typical caption should also identify the unit that produced the photography and, if appropriate, contain a file number. As an example, a typical caption may look something like the following:

UNIT ID	PACIFIC FLEET IMAGING COMMAND SAN DIEGO, CA
DIVIN, MEDIA CODE, FY, SEQUENCE NUMBER; DATE OF PHOTOGRAPHY	N0108-SCN-93-00374 21 MAR 1993
CAPTION TEXT	Six-year-old Terry Thomas, a victim of. . . Brenda has been doing . . .
CREDIT LINE	Official U.S. Navy Photograph by: PH3 Jon T. Boat USN

Your skill as a caption writer, like any endeavor, will improve with practice. When you write a caption, have the photograph in front of you. This may help you recall just what was taking place. Avoid phrases, such as-“Shown above,” “This is a picture of. . .” or “Posing for the camera . . .” These phrases insult the reader's intelligence.

When writing captions, you should always be alert to point out interesting or important things in the photograph that might escape the casual reader. Remember to spell out the meaning of all unfamiliar abbreviations. PHAA may mean Photographer's Mate Airman Apprentice to you, but it may be meaningless to the reader.

Finally, you must remember that the caption should supplement the photograph, not duplicate with words what is readily evident in the photograph.

Captions should always be typed, preferably double spaced, on a separate sheet of paper, such as “crack-and-peel” stickers or plain, white paper, and affixed to the back of the photograph. When using plain, white paper to prepare and attach a caption to a photo, first type the caption on the bottom of a sheet of paper. Cut off most of the unused portion and fold just above the typing. Attach the caption to the back of the photo with tape so the typed caption folds over the bottom and lies against the face of the photo. When unfolded, the caption is properly positioned at the bottom of the photo.

INVESTIGATION PHOTOGRAPHY

Photography is a valuable tool used by the master-at-arms, the Naval Investigative Service, and

other investigators to make visual records of crime scenes, accidents, or other incidents. Evidence (investigative or forensic) photography is used to show particular items of evidence and their relationship to the scene and to produce closeup pictures of significant parts of the scene.

As a Photographer's Mate, you usually will be working under the direction of an investigator when producing forensic pictures. However, you should take the initiative to learn all you can about the case you are working on. With sufficient information, you can use your judgment to assess the photography requirements, angles of view, supplementary lighting, close-ups, and other factors, such as camera, lens, and film choice. Investigators, especially in crime cases, are often reluctant to give the photographer any information. They would rather you not ask questions and just follow their specific directions of what to photograph. This is often the case because they do not want information leaks that could ruin their case. You must gain their confidence and not discuss the case with anyone outside of the investigative team. On many occasions, investigative leads have been developed solely by studying good forensic pictures provided by a professional photographer.

When photographing any scene as part of an investigation, it is important to make overall pictures of the scene that can be related to the close-ups which you must also take. These overall pictures are important and cannot be sacrificed for any reason. Use wide-angle lenses to obtain these views when you cannot move to a vantage point where a normal lens can be used. When making overall views of the scene, avoid having extraneous elements, such as people and automobiles, or other confusing elements included. Extraneous elements only serve to mislead people viewing the photographs and may obscure important details. Investigators will normally cooperate by clearing the scene for the overall views.

Never take it upon yourself to recreate the scene if it has changed before your arrival. Repositioning elements within the scene or having someone assume the position of a body that has been removed will not be of any help. There is no way of assuring accurate repositioning, and the photographs become suspect as being “contrived” and made up. You should always photograph the scene as you find it. If the investigator wants to recreate the scene, that is his business. You should not offer to help.

Closeup views of scene elements should be made of any evidence, weapons, aircraft damage, body wounds, and so on, before the evidence is moved. If, for example, a closeup shot is needed of a gun that was thrown under

a car, it should first be photographed before the car is moved. This overall or medium shot should show both the car in comparison to other scene elements and its relationship to the gun. Only then should the car be moved to get the closeup shot of the gun.

Today, the trend in Navy investigations is to use color film because color photographs represent the subject more realistically than black-and-white film. People see their surroundings in color, and based on this premise, color photography has become completely acceptable for courtroom use. Color pictures convey a more accurate representation of the facts to the court or persons reviewing reports.

FIRE AND ARSON PHOTOGRAPHY

Fire fighters and damage control personnel realize the value of good photographic records of a fire and its damage in helping determine both the cause of the fire and the effectiveness of the methods used to fight the fire.

One of the most important functions of any group of fire fighters is training. The most effective training method is, of course, actually practicing fire fighting. However, aboard ship and because of the cost ashore, this cannot always be done. The next best method of training is with visual aids. By studying still pictures and movies of a fire, firemen and members of the damage control party can receive instructions and observe proper procedures in the performance of their duties. Photography serves as a means of refreshing the memories of fire fighters and witnesses during the investigation of a fire.

Fires aboard ship and ashore should be photographed from the time the fire party arrives to the time the fire is out. Pictures of the fire should include overall views showing the positions of trucks, ladders, hoses, other types of equipment, personnel fighting the fire, and people watching the fire. Pictures of the progress of the fire must also be made. Fire progress pictures should show the structure, smoke, and flames.

Arson is becoming a big business in the civilian world. As sailors, we do not see much arson in the Navy, but there have been cases and will continue to be cases of arson in the Navy. We cannot afford to have an arsonist in our midst, particularly aboard ship or in the barracks.

Without evidence, arrest and prosecution of an arsonist is extremely difficult. Photography is an effective tool in recording and preserving the evidence of set fires. Much of the actual evidence may be destroyed during fire fighting, or if it survives the fire, it may be impossible to preserve.

Every effort should be made to photograph the scene of a fire, whether or not arson is suspected, before it is disturbed by other operations. You must work fast, but never do a careless job. Your pictures may be used to prove the intent to commit arson.

The pictures you make of a fire should do the following:

- Show the area or areas in which the fire started or was set.
- Help identify spectators. An arsonist often remains to watch the fire.
- Provide information about the speed of combustion and direction of spreading.
- Show the progressive stages of burning and fire fighting from various angles. If possible, keep a record of the time each picture was made.

Help investigators determine the type of material burning. This is where the use of color film is recommended. The steam, color, and quantity of smoke and the color and size of flames are indications of what type of material is burning. The color of the smoke often indicates whether an accelerant, such as gas, was used to speed the burning.

Once the fire is out, pictures (fig. 6-7) are made of the rubble. Give particular attention to the most burned or charred areas. The structure should be photographed from all sides to show the damaged areas. Other things to look for are incendiary devices and combustible materials, such as matchbooks, paper, liquids (such as gas and paint thinner), and fuses. Although they may have burned completely, there could be a visible trail, defective wiring, and electrical or gas appliances that may have been the cause of the fire.

The exposure required to photograph the interior of a building after a fire may be considerably more than indicated by normal exposure calculation methods. So much light is absorbed by blackened and charred areas that it may be necessary for you to open up several stops over your indicated exposure, even for well-lighted close-ups. When using flash to light burned areas, hold the flash away from the camera to permit some improvement in the rendering of texture. This will bring out the alligator or checked pattern of burned wood, blistered paint, and so forth.

AIRCRAFT ACCIDENT INVESTIGATION PHOTOGRAPHY

Every aircraft accident (fig. 6-8) affects readiness to some degree, and with the cost of equipment rising steadily, the loss of one of our first-line aircraft represents a serious loss to the Navy and to the national economy.

Aircraft accident investigation is one of the fundamental elements in a program for the improvement of aviation safety. Photography plays a major role in an aircraft accident investigation. The evidence obtained through photographs will help determine steps to prevent similar occurrences.

To make the most useful photographs, you must clearly understand the purpose of photography in an aircraft accident investigation. It is NOT to assess blame, nor is it solely to establish a single or primary cause factor. Few accidents result from a single cause. In most of the accidents, a sequence of events occurs. The elimination of any one of these events may have prevented the accident. Therefore, to prevent future occurrences, you must consider all possible cause factors and photograph them, if possible. An incomplete

photographic record of the investigation may result in erroneous conclusions and nullify the only possible benefit that could have been derived from a costly accident. The photography surrounding an aircraft accident is a methodical accumulation of small bits and pieces of information that eventually form a pattern. The wreckage itself may contain valuable evidence that, if correctly photographed, may provide these certain cause factors.

Successful aircraft accident photographers have certain essential characteristics in common. You must apply the following essentials of good aircraft accident photography to your work:

1. Promptness—Get to the scene of the accident immediately—before the evidence is disturbed.
2. Thoroughness—Photograph all evidence in minute detail. Operate on the assumption that there is no limit to the amount of photography justified to prevent the recurrence of one aircraft accident or the loss of one life.
3. Organization—Conduct a planned photographic survey.

Jim Bryant
302.280

Figure 6-9.—News reporters photograph damage incurred when a T-2C Buckeye crashed into the superstructure of the USS *Lexington*.

4. Accuracy—Pictures that show half-truths are unacceptable in aircraft accident photography. Do not make pictures that hide detail or distort the scene. Remember, all photographic evidence must be accurate.

It is nearly always necessary to crawl around or under the aircraft wreckage to get pictures. You should arrive at the scene appropriately clothed in a complete, comfortable working uniform, which you do not mind soiling.

Procedures at the Scene of the Accident

Current OPNAV instructions specify that the surviving crew members (if physically able to do so) or the first military personnel arriving at the scene of an aircraft accident must take charge until relieved by proper authority. At the scene of the accident, you will be working for the officer in charge (OIC). You report to and receive your orders from the OIC. In many cases, it may be possible for you to accompany the crash rescue party to the accident. The sooner an experienced and qualified photographer can get to the scene of an accident, the better the possibilities of acquiring more valuable photographic evidence. You should commence taking pictures immediately upon arrival. Pictures made before extensive fire damage can reveal information that might otherwise be lost.

Safety of personnel involved is of primary concern in every aircraft accident. Rescue operations and removal of occupants from the aircraft should be among your first photographs. When medical treatment is being given to survivors of the accident, photograph it not only for documenting the treatment but for the purpose of isolating factual information on human failure. Casualties should also be photographed in the positions they occupy when you arrive on the scene. Photographs of the dead should be made to show the location of the wreckage and the position of each body in relation to it.

You should be advised of any classified material involved, and it should be either covered or removed before photographs are made unless it is important to the accident investigation. This is a situation where close liaison with the OIC is absolutely necessary.

News reporters may gather at the scene and because you, as a photographer, have something in common with them, they will naturally seek you out. Do not attempt to tell a reporter what to write. Do not make a statement, express an opinion, or provide information about the accident (fig. 6-9).

Photographic Record

In almost every accident, a certain minimum number of photographs is usually required. These apply to automobile, motorcycle, personal injury, or any type of accident.

PH2 John Gay
302.281

Figure 6-10.—USS *White Plains* is blown hard aground at Polaris Point, Apra Harbor, Guam.

A complete photographic record should include photographs of the general terrain or site of the accident, overall views of undisturbed wreckage, reconstructed components or systems, and closeup views of important or significant structural or other material failures. The terrain pictures should show any surface irregularities, presence of damage to buildings, trees, or other objects, point of first contact, impact marks, and so forth. The photographs should be made as soon after you arrive at the scene as possible, since subsequent investigation work or other conditions may alter or destroy the evidence. After the terrain pictures have been obtained, you should concentrate on photographing the undisturbed wreckage. The emphasis here should be on showing the attitude of the aircraft or vehicle at the point of impact, the general extent of damage, and the presence or absence of all major components, such as the wings, stabilizers, elevators, rudder, and ailerons.

When fire indications are found in various areas of the wreckage, show these indications together with any corresponding indications of tire in the surrounding area. These later photographs can often be used to substantiate findings of ground fire versus in-flight fire. Other points that appear to be significant from a preliminary examination should be recorded before the detailed wreckage examination is begun. Very often the investigator decides to reconstruct or rearrange particular parts of the wreckage to determine failure patterns. A photographic record should be made of such reconstruction work to assist in the subsequent evaluation. Finally, closeup views of important structural failures should be included in the photographic record.

In general, the photographic record should be complete enough to permit a person who is reviewing and evaluating the accident report to appreciate the

significance of the investigator's finding. While the investigator's report must contain a detailed write-up of the damage, it is still true that one picture can often take the place of many words (fig. 6-10). The investigator should use photographs as another tool in complete and accurate reporting. Each photograph included in the report should purport to show a separate point or detail relative to the accident.

When evidence is to be presented, get a good picture of it. You are not a mind reader and cannot be expected to get the pictures that are contained only in the investigator's mind. Normally, you must ask the investigator exactly what is to be photographed.

Pertinent photographs of the following details are always required:

- General view of the scene along the wreckage pattern to the point of first contact.
- ✦ Aerial view of the accident scene (aircraft).
- Damage to objects struck
- ✦ BUNO or license plate.
- ✦ All major parts of the wreckage.
- ✦ Detailed view of the cockpit, instrument panels, switch settings, and control handles (aircraft).
- ✦ Engines and propellers.
- Wheels and landing gear assemblies (aircraft).
- ✦ All parts involved in, or suspected of structural failure, or of having contributed directly to the accident. These photographs should have sufficient detail to show the grain of the metal at the failure point or other detailed information, such as the direction of shear of the rivets.
- ✦ Any failed part that has been established as the cause of the accident or is believed to be significant to the cause of the accident should be photographed in detail.

When photographing small, important pieces of evidence, the parts should not only be photographed in the field but they should be removed from the scene and photographed in the studio under controlled conditions. This ensures that the photographs of the items in question are clear and well defined. It is a good practice to photograph the failed part and an undamaged like item in the same exposure so the failure is readily apparent.

To avoid confusion, you should assign all aircraft accident photographs exhibit numbers and carry descriptive captions to point out the details of evidence

to which they contribute. A picture without an explanation is confusing and worthless.

Each aircraft accident photograph should be readily identifiable, and to ensure this necessary requirement, you must identify all photographs with the following information:

- ✦ Date of accident
- Location of accident
- Type of accident
- ✦ Type of aircraft
- ✦ BUNO of aircraft
- Part and part number (where applicable)
- ✦ Squadron
- ✦ Aircraft accident report number

Special handling note according to OPNAVINST 5290.1

At a minimum, the following items should be included in your camera bag for an accident or arson scene:

1. Camera and normal lens
2. Wide angle and telephoto lenses
3. Flash unit and extra batteries
4. Large amount of color and black-and-white film
5. Extra sync cord for the flash
6. Flashlight
7. Note pad and pen
8. Macro lens or closeup filters
9. Surgical gloves
10. Ruler
11. Tape measure

PRODUCT PHOTOGRAPHY

Product, or illustrative, photography is used to show and explain an object more completely and concisely than is possible with words alone. By using the photographic medium, it is possible to illustrate a variety of items to show size, shape, location, and condition. In the Navy, product, or illustrative, photography is used to show new equipment—from ships to pencil sharpeners and from buildings under construction to damaged

aircraft. It is used extensively to show damaged, defective, and unsatisfactory equipment-from aircraft engines to zippers.

The discussion on illustrative photography in this chapter is limited to those aspects that apply to studio work. In this sense, illustrative photography should be considered as product photography. The techniques given here are not necessarily “locked up” in the studio. They can be taken outside the confines of the studio and put to good use in the field.

Product photography, then, is the making of photographs for the purpose of illustrating or explaining something about a product, either in whole or in part.

EQUIPMENT

The three types of format cameras and the lighting units used to accomplish product photography are discussed in this section.

Camera

The variety of subjects encountered in product photography requires a camera with a long bellows extension, vertical and horizontal swing adjustments, tilt, rising front, and lateral shift and both long- and short-focal-length lenses. All of these features exist on a view camera.

The view camera is the primary tool of professional product photographers. An 8x10 view camera is usually the largest size in use today. Photographers that want to produce the highest quality photography use it. Its large film format and adjustments help to produce clear, sharp, nearly distortion-free photographs that are in complete focus.

Large film-format cameras provide high-quality images because the negatives or transparencies do not have to be enlarged as much as smaller negatives. A large film format in and of itself does not necessarily ensure high-quality product photography. Long tonal range, from highlights to shadow detail, is required. Lighting ratios must be calculated and adjusted with care, and exposure calculations must be precise. Lenses of the highest quality, which are spotlessly clean, enhance the photographic quality of any size format.

VIEW CAMERAS.—Most Navy photo labs do not have an 8x10 view camera; but most of them do have a 4x5 view camera, and you should use it for most product photography. Whatever view camera you use, it **must** be supported on a steady tripod.

MEDIUM-FORMAT CAMERAS.—If for some reason, such as a need for speed or limited working space (such as inside the cockpit of an aircraft), a view camera cannot be used for product photography, then a medium-format camera should be your next choice.

Some photographers choose other than a large format camera simply because they are willing to sacrifice quality for convenience, rather than use a view camera. They probably have the attitude of “it's good enough for government work.” Do not fall into this trap. Instead, always strive to produce photography of the highest professional quality. As we have said before, you will be known by the quality of your photography more than anything else. Maintain the attitude that “nothing is too good for the Navy.”

Medium-format cameras can be hand-held, focused rapidly, and many images can be produced in a relatively short time. The film size, however, is not as conducive to high-quality photography as the 8x10 or 4x5 formats. The main disadvantage of a medium-format camera for product photography is its lack of adjustments to correct distortion.

35MM CAMERAS.—Finally, we have the small format, 35mm camera. Because of its small film size, many photographers do not even consider it for use in product photography, particularly in the studio. It does, however, have its place in product photography, particularly when a large number of exposures must be made in rapid succession or when working space is very limited; for example, inside the intake ducts of a jet aircraft.

Which of the three format cameras—large, medium, or small format—should you use for product photography? There is no **best** camera to use; there is, however, only one **best** camera to use for each assignment, and you must be able to choose the one that best meets the needs of the photographic assignment at hand.

Lights

The lighting equipment most commonly used for product photography is incandescent lamps and electronic flash or strobes. All lighting units have one or several of the following means of controlling light: reflectors, lenses, barn doors, diffusers, snoots, umbrellas, or reflector boards.

SPOTLIGHTS.—Spotlights are one of the most important lights in small product photography. They produce light with a relatively high intensity and a well-defined, sharp quality. The rays of light produced by the Fresnel lens of the spotlight sharply separates the highlights from the shadow areas. A spotlight can create a visual sense of subject shape and bulk. When used in a skimming or crosslighting fashion, it renders sharp, crisp texture. Because the light rays are collimated, or parallel, with little flare or spillover, a spotlight produces high contrast. One great asset of spotlights in product photography is the controllability of the lights. The light can be controlled to highlight or isolate an area of the subject. Unwanted spillover into other areas can easily be avoided. Through proper use of accessories, such as snoots and barn doors, the control can be greatly extended. A disadvantage of spotlights is the harsh quality of highlights produced on some subjects. Bright spots on the subject may be pinpointed and hard to avoid. Nonetheless, a spotlight is a most effective main light for product photography.

FLOODLIGHTS.—In product photography, floodlights are used to cover a large area with relatively even illumination. The quality of light from a floodlight is very much dependent on the reflector surface. Polished, metallic reflectors produce a specular, sparkling quality, while matte-surface reflectors produce a softer quality of illumination. The quality of illumination from a floodlight is also dependent on its distance from the subject. At a given distance, the spread pattern for a given light unit is almost even. Some units may produce hot spots when used too close or too far from the subject. The larger the reflector and the closer it is to the subject, the more diffused the light becomes.

BOUNCE LIGHT AND UMBRELLAS.—The use of bounce light for product photography produces a pleasant quality. The light, because it is coming from one general direction, not an obvious source, surrounds the subject with soft illumination, gently enhancing curves and shapes while producing soft but distinct shadows. Bounce light can be used for either overall illumination or as fill illumination.

Umbrellas, being large and somewhat parabolic in shape, are more efficient than plane or board reflectors.

FUNDAMENTAL PRODUCT LIGHTING

Given a product assignment, you must determine ways to photograph or present the subject best. Aside from product arrangement and picture composition,

which must lead to an understanding of the purpose of the picture, you must first deal with the lighting. By the correct use of light, you can create a natural lighting, which is attractive, and simulates outdoor light. In product photography, you should always strive to produce lighting that appears natural, as though the product was illuminated by natural sunlight. After all, it is natural daylight by which all light is judged. Illumination from the main light should come from above and somewhat behind the subject, usually from about a 40- to 60-degree angle. In many commercial texts the main light is also referred to as the key light; these terms are used interchangeably by professional photographers. There should be one definite light source and only one set of dominant shadows, and the shadows must be illuminated sufficiently so the shadow detail is maintained in the film image. In a naturally lighted outdoor scene, this shadow detail is preserved by general skylight illumination. In the studio, this shadow detail is preserved or created by the correct use of soft, diffused, fill lights or reflectors.

In the studio, you can create the lighting effect of an overcast sky with a light tent or by using indirect lighting. This type of lighting is especially useful when you are photographing shiny products, such as bare metal and glass.

Backlighting is one of the essential tools in product lighting. Establishing the main light behind the subject often helps present three-dimensional form better than frontlighting. Aside from the subject being rimmed with light, which separates it from the background, the foreground shadow duplicates the shape of the object, making it easier to identify.

LIGHTING BASIC SHAPES

Most small product items fall under two basic or general shapes: rectangular and spherical. The illustrations in the following paragraphs show ways that basic lighting can be used to present shape. Although a perfect rectangle and a perfect circle are used in the illustrations, they are not intended to limit your lighting setups. You must, of course, make lighting adjustments, depending on how rectangular or spherical the subject is and the way you want to present it.

Lighting Rectangular Shapes

Rectangular- or box-shaped products can be lighted with just three lights—a spotlight from the rear and two floodlights, one on each side of the camera.

Two floodlights, one on each side of the camera., at camera level “flatten” the subject.

Diffused light from above does not help. There is no contrast between the two front planes.

Instead, start the lighting slowly, one light at a time. Here the left-front floodlight starts the lighting.

The spotlight from the rear is established.

Now add the third and final light. This is the right-front floodlight that should provide only about half the intensity produced by the other floodlight. Notice the background shadow and the way it helps to separate the subject from the background; also, notice each plane of the subject has its own tonal quality, giving it shape and form. The foreground shadow, besides helping to visualize shape, tends to hold the block to the ground.

Lighting Spherical Shapes

Spherical- or round-shaped products can be just as simply lighted, but this time the basic setup requires five lights.

With only the background lighted and no light falling on the ball, the ball appears as a hole cut in the background paper.

To light a round object, start the lighting setup by first establishing the main spotlight high, behind, and to the left of the subject.

Add a smaller spotlight at subject level in a position at the left rear of the set.

Adding a low, third spotlight from the right rear forms a bright highlight in the top of the area lighted by the main light. This adds a sense of roundness to the ball.

The final light in the setup is a weak fill-in light that changes the effect and produces a fully lighted ball that shows maximum shape, form, and texture.

Through experience, you will learn what effects to expect from lighting. Good lighting is created through an orderly, thought-out process involving several steps that should be taken in chronological order:

1. **Previsualize.** You should form a mental picture of how the subject should look. What should be shown? What part of the subject should be featured or be the center of interest?

2. **Determine** what type of lighting to use. From what direction should the main light come? Where should the fill lights be located? From what distance should the light come?

3. **Select** the equipment that can best do the job. What camera 4x5 inch, 8x10 inch, 2 1/4 inch, or 35mm? What kind of lights-strobe, incandescent, flood, or spot? What accessories are needed-reflectors, barn doors, umbrellas, and so forth.

4. **Establish** the lighting. Is the key light doing what you want? Would another light do a better job? Is there enough shadow detail? Is more or less fill light needed? Are there too many highlights and are they in the right places? Are the highlights too bright? Do each of the lights add to the overall quality of the lighting, or can some of them be eliminated? Will the subject record on the film as previsualized?

5. **Determine** the exposure. What should be the exposure for the highlights and the shadows? What is the correct exposure for the overall set? Will the film record the contrast range between important highlights and shadows?

6. **Check** the set. Is light spilling onto the camera lens causing flare? Is the composition as it should be? Are important details obstructed?

7. **Expose** the film.

CREATING THE LIGHTING

For most product photography, the first light to be placed is the main light, then lights to create highlights are added, and finally any fill lights. However, the order in which the lights are placed depend somewhat on the subject to be photographed. When, for example, the product is tented, the procedure should be to establish an overall, high level of illumination first. Other lights should then be added to better show shape, form, and bulk of the subject.

You should always start your lighting setup with the main light. The usual position for the main light in product photography is high and somewhat behind the

subject. The position of this light is very important. To establish this light, you should do the following:

1. Darken the set.

2. Through the camera ground glass, view the effect of the main light on the subject. Have an assistant move the main light in the general area previsualized for the main light. Establish the main light in a position where it produces the most pleasing and desired effect. Remember, the farther the main light is from the subject, the smaller the highlights and the sharper the edges of the shadows. As the light is moved, notice the change in highlight and shadow areas. It is important for you to observe the effect of the lighting (through the ground glass) exactly as the camera will see it. The characteristics of the main light greatly influence the overall quality of the picture.

3. Add secondary spotlights as needed to create highlights and texture. Highlights other than those produced by the main light may be needed to help separate and define subject planes as well as to separate the subject from the background or its surroundings. By using secondary spotlights in a crosslighting or skimming manner, you can emphasize the surface texture of the subject.

Establishing the secondary lights to produce the desired highlights and texture is more time-consuming than positioning either the main or the fill lights. When the subject is a complex shape or has many planes, several small, secondary lights may be needed.

4. And finally, once the main light and highlights have been established, the fill-in illumination is applied to provide the appropriate shadow detail. The fill light illumination is usually supplied by one or more diffused floodlights or reflectors. Care must be taken to ensure that the fill-in lighting does not cast distinguishable shadows. This problem can generally be solved by positioning the fill lights close to the camera and at a low angle or about tabletop height.

Every light you use in product photography should have a definite purpose in creating the final photograph. A dominant light source must prevail without undue competition from other light sources. If the addition of a new light creates new problems, then start over again. Remember, the simplest approaches to product lighting are the best.

Lighting Ratio

Whenever you light the set for small product photography, you must keep lighting ratios in mind. A

302.187

Figure 6-11.—Using painted light.

useful range between highlights and shadows, in which the film can record detail, must be established. This useful range depends completely on the reflectance range of the subject.

With most color films, this range between highlights and shadows must be kept within five f/stops. This means a ratio of about 32:1. Any area of the subject (except specular highlights) that is outside of this range is reproduced either too light or too dark in the final picture. A reflected light meter can be used to find the relationship between the useful or desired diffused highlight and the darkest desired shadow. A difference of two f/stops is a scene contrast of 4: 1; four stops is a 16:1 contrast. Most black-and-white film can record both highlight and shadow detail when this range is not greater than about six f/stops.

Painted Light

Painted light (fig. 6-11) is one of the best ways to obtain even illumination and soft shadows. With this type of lighting, only one light is used. The light is moved constantly up and down and around the subject and its background. Painted light is effective for illuminating subjects made up of many smaller parts that cast shadows onto adjacent parts, such as printed circuits or the inside of a radio.

When you are using the painted light technique, the exposure must be increased by a factor of 3. To determine the painted light exposure, hold the light stationary at the same distance it will be used from the subject. Read the exposure with your light meter. Multiply the exposure time indicated by the meter by 3, the painted light factor.

Example: With the light meter, you have determined the exposure to be 6 seconds. Multiply the exposure time, 6 seconds, by the painted light factor, 3 ($6 \times 3 = 18$ seconds).

The minimum exposure time required when using painted light is 10 seconds. An exposure of less than 10 seconds does not give the photographer enough time to illuminate the subject evenly.

PRODUCT PHOTOGRAPHY TECHNIQUES

Product photography requires patience and a keen eye. The slightest change in lighting or subject placement can add to or subtract dramatically from your photograph. Pay particular attention to small details of your photograph because this helps to provide sharp, high-quality images with fine detail.

Figure 6-12.—Tent lighting setup.

TENTING

Photographing small products can be quite difficult if they include bright reflective surfaces. You can easily see other nearby objects reflected in them and sometimes even the whole studio. Also, light from the lighting units may reflect off the surface very strongly at a particular point. This can create an unwanted bright highlight. There are two ways to get around these problems. You could use many lights and add reflectors to make sure the lighting is even. This may solve the problem of light from the lighting units reflecting off the subject surface, but unfortunately there are two great disadvantages: it requires more lights than most photo labs have, and you still have reflections. The other way to solve the problem is to use the tenting technique.

The tent consists of a frame covered by a translucent white material that casts a diffused illumination on the subject (fig. 6-12). The lights are placed outside the tent and directed onto the translucent material. The color of the background, which is placed inside the tent with the subject, depends on the subject and the effect desired. Strips of black or colored paper taped to the inside of

the tent add the necessary dark accents or “bring to life” a colorless object.

DULLING REFLECTIONS

Another way to control reflections is to use a matte spray or dulling compound. Matte spray comes in a pressurized can and is useful for the high gloss of highlights on shiny, metal objects with curved surfaces. When used, the spray should be applied to the entire surface of the object. However, do not indiscriminately spray all types of surfaces. The spray may damage some finishes or plastics. When used on metal objects, it can easily be wiped off after the picture is made. Matte spray can also be applied to the back of a glass of clear liquid to cause the backlighting to spread more evenly over the back surface.

Cosmetic eyeliner, applied with a soft makeup or camel-hair brush, can also be used to help control reflections.

237.221

Figure 6-13.—Using a mirror to show both front and back of the subject in one photograph.

USING A MIRROR

It is often difficult to set up a camera for interior and closeup work to obtain the most desirable viewpoint. Space limitations or pieces of equipment may obstruct the view and make it impossible to photograph an assembly directly. Frequently, a mirror can be used to your advantage in product photography. A mirror placed at the proper angle and distance shows the opposite side of an object in the reflection, while the camera records the front side directly (fig. 6-13). For example, in photographing an object for damage assessment where the damage is on two or more surfaces, you may find it difficult or impossible to show all the damage in one view without the aid of a mirror. In such cases, the value of a picture may be greatly increased by showing all of the damage in one picture. One instance would be in photographing a cylinder that has been scored or cracked on the inside as well as damaged outside. Both surfaces may be shown in one view by using a mirror.

You may often find it desirable to obtain a picture of an object or part that shows its relation to the complete assembly. When it is impossible to position the camera and see the part or object directly, the problem may be solved by using a mirror to reflect the image of an assembled part.

Taking a picture of a reflected image presents some problems that are unique to mirror photography. It is difficult to prevent the mirror from reflecting other objects that are not wanted in the picture. You must be careful and place the mirror at the proper angle to eliminate unwanted reflections. When arranging the

237.222

Figure 6-14.—Exploded views.

lights, avoid illuminating an object that produces undesirable reflections. Often a screen can be set up to block the reflection of unwanted objects.

Correct lighting of an object for mirror photography is slightly more difficult. Lighting on both the front and back sides of the object must be evenly balanced; otherwise, the mirrored image appears too dark or too light. Direct the light on the object from the mirror side as well as the camera side. When it is impossible to place a light on the mirror side of the object, use the mirror to reflect the light onto the back side of the object. This requires careful placement of the camera in relation to the light source to avoid strong rays of light from entering the lens. Spotlights are usually more suitable than floodlights as sources of illumination, because a beam of light is easier to control.

Focus the camera carefully when photographing a reflected image. Usually, it is necessary to use a small f/stop to increase the depth of field sufficiently. When focusing on a reflected image, the lens must be set for the distance from camera to mirror PLUS the distance from subject to mirror. This naturally requires a much greater depth of field than is ordinarily required.

EXPLODED VIEWS

Occasionally, exploded views (fig. 6-14) of small objects are photographed in a group to show the various parts of an assembly. Normally, they are arranged in the layout in the same order in which they are assembled or disassembled. Pay particular attention to the composition of objects as they appear on the ground

glass, rather than as they appear to the eye from the camera position. Attempt to arrange them so they fill the picture area in an interesting manner. Do not arrange them in a long, narrow line with black space above and below them.

Exploded view photographs provide the viewer with positive identification of the many parts and pieces that make up a given machine, instrument, or manufactured assembly. When photographed on a light box, you can illuminate the shadows. The various parts, shown in order of assembly, appear to float in the air in correct alignment and perspective.

A substitute for the light-box background is a sheet of plate glass firmly supported approximately 20 or 24 inches from the floor. Two floodlights, directed from either side of the glass, bounce light evenly from the white seamless paper on the floor up through the glass.

Preparing the Parts

Disassemble the parts carefully so they can be laid out in order of assembly. Clean each piece thoroughly, removing any lubrication or foreign deposits. Lay the parts out as they are to be photographed, and study each piece before you proceed. Large areas of stainless steel or bright metal should be sprayed with a dulling spray to prevent objectionable "hot spots." Smaller areas can be treated with an eyeliner.

Where edges or screw holes do not show readily, they can be edged with a black grease pencil. Conversely, when the part is dark, white pencil or chalk can be used to define it.

Setting Up the Parts

Place the parts on the glass in order of assembly. To stand small parts up, mount them on a small strip or square of acetate with a little beeswax supporting the piece from behind. Even the smallest screw should be mounted on a base so it can be slid into exact position later. The base should be cut as small as possible so it does not interfere with other parts lined up close to it. Heavier pieces can be mounted on small squares of glass.

To obtain an illusion of height, you can move the parts away from the camera. There is a limit to this procedure, however, and when a part becomes too small in relation to others, it should be elevated. Various size blocks (painted flat white) and, in some cases, glass shelves or long, narrow strips of glass are sometimes used.

Camera Angle

For the majority of subjects, the most desirable camera angle is 45 degrees above and to the side of the assembly. From this vantage point, you can see the top, side, and end of most parts.

PHOTOGRAPHING GLASS

In photographing glass, it is the background and reflections from the background that light the glass. Glass objects can be pictured clearly by lighting them in such a way that they stand out as dark outlined shapes against a light background or as a light outlined shape against a medium or dark background. These techniques of lighting are actually variations of a basic silhouette method.

The Set

The setup for photographing glass products consists of white seamless background paper. The background paper is curved forward on the floor so it is completely underneath the area containing the setup. Place two supports, such as sawhorses or tables, on the forward part of the background paper. The supports should be spaced to hold a sheet of plate glass. The plate of glass gives you a transparent worktable through which light bounced off the background paper in back of and underneath the glass product will pass. Strips of colored or black paper can be attached, out of camera view, to the background paper for edge effects to the glass products.

Because the light reflected from the background is usually the only source of illumination, the film exposure is relatively long. Proper camera equipment and a sturdy tripod are necessary to prevent movement during the rather long exposure.

The height or camera angle varies for different subjects and showing the ellipse or oval of the rim adds depth and roundness to the picture, since most glass items you photograph are three-dimensional.

Lighting

You should be able to darken the studio completely. An overhead light, an exit sign, or even a light leak around a door can cause problem reflections. And not eliminating unwanted reflections results in much time and effort wasted.

Lighting glass products (fig. 6-15) is mostly a matter of personal taste. It can be learned by practice and by

302.188

Figure 6-15.—A typical setup for lighting glassware.

studying photographs of glass items. When you are studying pictures of glass objects, notice how all the good pictures were made using variations of basic silhouette lighting. You will find it is easy to produce an infinite variety of effects by simply changing or redirecting the bounce light from the background.

In photographing glass there are no hard-and-fast rules for the placement of lights. The lights should, however, be placed with great care. Changing the angle just a little can drastically change the lighting effect and at the same time cause flare problems. When the lights are positioned to cause a great deal of reflection from the background and this reflection is uncontrolled, it may cause lens flare and result in flat negatives. Lens flare can be controlled or eliminated by erecting a black tent to extend from the lens board to the subject. This tent must be kept outside the angle of view of the camera. A focusing cloth draped over wood dowels works well. When photographing glass products, you should always use a matte box over the camera lens.

When the lighting produces a true silhouette, some highlights (fig. 6-16) may be desired to add sparkle to the glass. This can be done by using front bounce light from a narrow, diffused light source. To create such a source, attach a piece of white mounting board to one barn door of a floodlight and control the width of the light beam emitted with the opposite barn door. This narrow beam of light can be placed on either side of the camera and should be at camera level or higher. The

spacing between highlights on a cylindrical object, created by this method, can be controlled by moving the light closer to or farther from the lens axis. Do not allow highlights to obscure etching on the glass.

Exposure

To determine the exposure for photography of glass objects, you should take a normal reflected exposure meter reading of the background and increase the indicated exposure by four times.

Black-and-white film should be given a shorter than average developing time because the lighting ratio is usually very great, and excessive contrast will result with normal development.

Figure 6-16.—Adding highlights to glass products.

302.190

Figure 6-17–Sandwiching two negatives to eliminate the background.

BLOCKING OUT A BACKGROUND

It is a simple matter to eliminate or block out an unwanted background in product photography. The technique involves two negatives. Two separate pictures are made of the product setup. One exposure on continuous-tone film is made of the product lighted normally. A second exposure, on high contrast line-copy film, is made of the object silhouetted against a well-lit white background. The two negatives are then sandwiched together and printed.

The setup for this procedure is much the same as for a straight product picture. The lighting, however, is a little different. Figure 6-17 shows a typical setup for this two negative technique. The procedure is as follows:

1. Support the product so it cannot move between the two exposures. Use a small support because it must be opaqued out of your line copy or background negative. A light table may make a good support, but when some other support is used, keep it far enough from the background so the background can be lighted separately.

2. Light the product to provide maximum detail. Do not worry about objectional shadows on the background or visually separating the product from the background. In fact, with this technique, lighting that separates the subject from the background may cause a loss of detail at the edges of the subject.

3. Use a white paper background that is large enough to fill the camera view. The background illum-

ination must be very even because the high-contrast film used to make the background negative has a short exposure latitude.

4. Use continuous-tone film to make the subject negative. Use Kodalith Ortho film to make the background negative.

5. It does not matter what exposure you make first. However, each exposure must be treated separately. Only the lights for the exposure being made should be turned on.

6. Because lenses can shift focus at various f/stops, the same f/stop must be used for both exposures and the camera must be rock steady—it cannot move between exposures.

7. Load one film holder—one side with continuous-tone film and one side with high-contrast film.

8. Make the exposures. When you are making the background exposure, be certain there are no specular reflections bouncing off the background onto the subject, and use only the background lights. When making the subject exposure, use only the subject lights.

9. Process continuous-tone film and line-copy film as recommended in the *Photo-Lab Index*.

When you include a ruler (fig. 6-18) in the scene in product photography, especially for damage reports or forensic purposes, it indicates exact scale and simplifies printing the photograph to exact size.

PH3 Yvonne Albritton
302.191

Figure 6-18.—Ruler included in product photograph.

CORRECTIVE PHOTOGRAPHY

Corrective photography is the correct representation of three-dimensional objects on a single plane (the photograph).

At one time or another, you have probably taken a picture with the camera tilted up or at an angle to the subject, and you probably learned by experience what the resulting distortion did to an otherwise good picture. Most of the cameras you use on location do not have movements or adjustments for correcting vertical or horizontal distortion that is created when the camera is tilted or used at an angle to the subject. Such inflexible cameras do not allow you to present the subject correctly from any camera position that shows two or three sides of the subject. For the correct presentation of such subjects, camera movements must be used. Many students of photography, as well as many **self-acclaimed** pros, are inclined to use cameras lacking the essential advantages (camera movements and adjustments) of a view camera. Instead they use their “regular” camera for every assignment even when a view camera is the **only** correct camera for the job. Refer to chapter 4 to re-familiarize yourself with the view camera. Figure 6-19A and figure 6-19B show the

difference in uncorrected and corrected vertical distortion.

ARCHITECTURAL PHOTOGRAPHY

Architectural photography are pictures of man-made structures, especially buildings. These pictures may be made for planning, construction progress, illustrative purposes, inspection and survey, and other similar purposes.

PLANNING PHOTOGRAPHY

Architectural pictures made for planning purposes may fall into several categories. For example, the civil engineer working with an architect on design plans for a new commissary store at the naval air station may need a picture of the commissary store at the naval shipyard to show the architect the general concept of how the new store is to look. The engineer may also need the same picture plus pictures of other buildings near the proposed construction site to be included in the contract bids. These planning pictures may have to show obstructions to heavy equipment, or where the new store will be located in relation to other buildings, proposed and existing. The architectural pictures you make may be presented to the U.S. Congress for allocation of new-construction funds.

CONSTRUCTION PHOTOGRAPHY

Construction progress architectural pictures, (fig. 6-20A and fig. 6-20B) or simply construction progress pictures, are used as proof of construction progress from architect-to-builder-to-Navy. Whenever buildings or facilities are being built, a photographic record of the project should be made. These pictures may show whether the contractor did or did not follow specifications as written in the contract. They can also serve as a visual record of the material used in construction. In addition to their normal preservation as part of the construction contract record, they form the basis for periodic reports to higher echelons, including Congressional Armed Services Committees. Some of these pictures may be of great historical value, but their most important function is to serve as documentation for construction work.

For a complete record, pictures must be taken at intervals throughout the construction period. Excavation, foundation work, and the roughing-in process progress slowly; pictures made every 7 to 14 days, starting at day one, may be adequate to show this

phase of the work. The rest of the work may go more quickly and require pictures every day or so.

For an accurate record of construction, the pictures are usually made from the same camera position from day to day. However, as construction progresses, it may be necessary to make additional views, both exterior and interior.

The person for whom you are doing the photography should explain any special effect desired in the pictures; for example, accenting structural texture, highlighting a specific construction detail, pinpointing an architectural feature, or concentrating on an exceptional landscape view. And do not forget to make the last picture-the one that shows the completed project. We do not mean the one made the day the contractor removed his last hammer from the jobsite. Of course, you made that picture. We mean take a picture several months after the project is "finished," when the grass is green and the trees are planted.

The same care you give to other types of photography should be given to construction progress photography. Do use good composition and lighting techniques and other similar applications of professional photographic skill. Take particular care with shadow areas that may contain important details.

ILLUSTRATIVE PHOTOGRAPHY

The uses of illustrative architectural pictures in the Navy vary greatly. The commanding officer may want pictures that concentrate on overall design to show at a meeting with the admiral. The civil engineer may want pictures that show functional aspects of a building to be included in a report, and the operations officer may want a picture of the operations building, crash and rescue fire house, and the control tower to decorate his office. The editor of the station paper may need pictures that show a building before and after a self-help project. And, of course, the publisher of *Welcome Aboard* wants a picture of the BEQ and the mess hall. All these pictures are considered illustrative architectural photography and should be made to show the buildings to best advantage.

This type of photography is best done with a view camera so horizontal and vertical distortion can be overcome as much as possible. When making this type of picture, be sure there are no distracting elements in the picture area. The foreground and background should be clean. When possible, have all the windows and doors the same; for example, the windows should all be open or closed and the same for doors. When the windows

Figure 6-20A.—Construction in progress.

133.499

Figure 6-20B.—Construction in progress.

133.500

have shades or blinds, they should also all be in the same position.

INSPECTION AND SURVEY PHOTOGRAPHY

As with the other types of architectural photography-buildings or facilities-inspection and survey pictures play an important role in the Navy. The Naval Investigative Service (NIS) may need pictures of a building to point out weaknesses in physical security. The fire department uses pictures of the station theater to train the fire fighters in evacuation measures. And the safety officer certainly needs good pictures to show the extent of damage or existing hazardous conditions to buildings or personnel.

Exterior Photography

Buildings must be photographed pretty much as they exist. With portraits, for example, you can ask the sitter to smile and pose, and with still life you can alter the arrangement. You cannot do either of these with a building. The main controls you have over the picture are the viewpoint and the lighting.

For exterior architectural pictures, the position of the sun in relation to the subject is a very important consideration. Which sides of the building are lighted and at what time of day? Where are the shadows cast?

Architecture is dead without light. Like the sculptor, the architect shapes forms in relation to lighting. The lighting at a site is often studied long before the first plans take shape on the drawing board. The lighting becomes a deciding factor in determining the character of a building, the choice of materials, and the location of the building.

The nature and direction of the light are the two main components of our concept of lighting. "Normal lighting" is often preferable for perfect reproduction of materials; that is, light from a slightly overcast sky. This diffused light reduces contrast in the texture of the material just enough to create a good balance between the highlights and shadows. A building as a whole is often depicted better in direct, angled sunlight from a cloudless sky. Filters are used to control the contrast between subject and sky. Direct sunlight often produces contrasty pictures with simplified lines that may sometimes be preferable as an illustrative effect. The light in cloudy weather is the worst kind of lighting for architectural photography. Try to avoid making pictures of a building in cloudy weather. The direction of the light on sunny or slightly overcast days governs the form of

the building and the ability of the photograph to bring out its characteristic features. Since the position of the sun in relation to the building constantly changes, there is only one way to determine the best lighting-study the building at different times of the day. Only then is it really possible to identify the best lighting for the building. Moreover, you should be prepared to study the lighting from different angles. Do not be content with your first camera angle. You should always check to see whether there is a better angle.

A building should be depicted so the viewer experiences its volume and materials. This is often impossible, except with side lighting. The greater the angle of the light, the greater its ability to produce a forceful re-creation of materials and shapes (fig. 6-21).

Also to be considered are the surroundings. Is there construction going on in the background? Is there a distracting landscape or unrelated building that must be concealed? What is the best camera position for making this particular picture? Can I get far enough away to present an undistorted image? Should I have a ladder to stand on or can I make this picture from on top of another building or must I arrange with public works for a bucket truck? What number of viewpoints are required? What focal-length lens is best for each view?

Viewpoint

The greatest difficulties in photographing buildings is converging verticals. When you hold the camera so it is pointing horizontally, you often find there is too much uninteresting foreground included in the picture, and you may be "chopping" the top of the building off. So, tip the camera back to eliminate most of that foreground and get the top of the building back into the picture. Now, look what has happened-the vertical lines are converging; they are no longer parallel; they are sloping in at the top of the picture. The picture is distorted. A good architectural photographer does not produce such a picture. Instead, he uses a view camera and does it properly.

Interior Photography

Photographs of interiors can be grouped under three headings:

- Public interiors of all kinds, such as assembly halls, places of worship, libraries, galleries, auditoriums, and theaters
- Residential interiors, both large and small

PHAN Wright
302.141

Figure 6-21.—Exterior architectural photograph shot with 45-degree lighting.

- Details of interiors, mainly close-ups of adornments, technical features, interior decorations, and so forth.

Photographs of public interiors are often characterized by size, dominance, scale, and measurements. You must be careful of fluorescent lights when shooting color film. They can produce color casts. If the fluorescent tubes are all of the same type, the color cast can be corrected with filters. Fluorescent lighting is, however, often excellent for black-and-white photography. In interior photography of public buildings, an attempt may be made to shoot from a somewhat higher camera angle than eye level to provide an overview of the scene. It is important not to have the first detail in the subject too far from the lower edge of the picture. The interior should glide into the image frame in a natural way. Maximum depth of field is the only acceptable technique here.

Another important problem in public and residential interiors is the balance between natural outdoor light and indoor artificial light. When lighting is mixed this way, it is better to delay shooting until the daylight is too weak to overwhelm the interior lighting. Using the light of the

midday sun is definitely wrong. It is also wrong to photograph interiors so late in the day that the sky seen through windows is completely black. So a time near sunset or, if you wish to avoid visitors, the early morning hours is recommended, especially for color photography. Measurement of the ambient interior illumination and the outdoor light gives you a good idea of the best time to take pictures. Lenses with built-in leaf shutters are major assets in interior photography when some daylight is present, because they synchronize with electronic flash at all speeds. The choice of a suitable shutter speed allows you to obtain balance between daylight and flash illumination.

INDUSTRIAL PHOTOGRAPHY

Photography is regarded as indispensable to Navy industry. You say you did not know the Navy was or had industry? Well, stop and think for a minute. How about the naval aviation depots, the public works centers, and the shipyards? The demands for good photography for research, development, documentation, and communication placed on us by these industrial types of

activities has made photography an integral part of the Navy's industrial framework.

You should be able to tackle just about any photo job that comes up. When shooting industrial photography, you must work closely with research and development engineers, machinists, and technicians far outside the realm of photography. You must be the master of photographic techniques, and have an eye for good pictures-plus imagination for creative photography.

Know Your Subject

Before a satisfactory photographic record of an industrial situation can be produced, you must have an adequate understanding of the subject. For instance, when you are called on to photograph a malfunctioning machine that is capable of performing several operations in the manufacture of an aircraft wing component, you should be told-better yet-shown, how the machine, or one like it, works. With this information, you are better able to shoot the malfunctioning machine and show what the problem is or what is causing the problem. Granted, you could probably make the picture if someone just pointed you in the right direction. It is not always possible to discuss each intimate detail of a problem, but it is certainly possible to make clear just what a photograph should illustrate. This kind of preparation is possible only when there is cooperation between the photographer and the requester. Coordination of photographic activities within an industrial organization promotes a better understanding between everyone concerned, and it leads to a more effective application of photography.

Safety Precautions

Photographers, like other people in and around industrial operations, must observe existing safety precautions. If your imaging facility does much industrial photography, it should have, as a minimum, a safety helmet and protective clothing available for you to wear.

An industrial photographer, like other photographers, must be able to move around to determine the best camera angle. You must also keep in touch with the people responsible for safety to avoid risks to yourself and others. The people in the

photographs must also be shown wearing their safety helmets, hearing protectors, and so forth.

The camera also must be protected. It is a precision instrument and should be given adequate care and protection. When in use, the camera usually does not need any more protection than the photographer. But it should be given extra protection when used in places exposed to flying sparks, spattering molten metal, and so forth. A skylight filter on the lens should always be used to help protect the lens. This filter does not affect exposure or color balance but does protect the lens element. Buying a new filter is a lot cheaper than buying a new lens.

A lens shade should be the constant companion of every lens. It keeps a lot of extraneous light from entering the lens and can also protect the lens from certain types of damage.

Photographing Large Machines and Equipment

The photography of large machines or equipment, such as hydraulic presses and aircraft during rework or ships during construction or overhaul, presents special problems. The bigger the equipment or unit, the more difficult it is to photograph.

In many instances, the equipment may be part of the industrial production setup and the picture making must be planned so it does not interfere with production.

Pictures may be needed at various stages of work to show wiring, piping, and components that are concealed during later steps of production. Pictures are able to show the location and methods of production and assembly. These pictures are often used to highlight certain aspects of work equipment failures, repairs, and modifications.

The Right Viewpoint

When you photograph large equipment or machines (fig. 6-22), a series of pictures is one of the best ways to cover the assignment. The larger and more complex the subject, the greater the need for a series of pictures. The series of pictures should be planned to record important details of the subject. The views to be considered are as follows:

- Plane views-show detail in various components and parts of the equipment

Figure 6-22.-Interior view showing machinery insulation.

237.210

JOCS R.P. Benjamin
302.282

Figure 6-23.—Catapult retraction system.

- ◆ Relationship views-show the relationship or association of various parts and components, one to another (fig. 6-23)

- ◆ Complete views-show the equipment from different angles

The plane view is made of an entire unit or, if the unit is very large, segments of the unit. Plane views are

also made of sections of large units to show greater detail. Along with the plane views, three-quarter views may be needed to show the relationship of unit parts that do not appear in the plane views. Complete overall views of the subject are often made from a high viewpoint. An oblique view from a high vantage point often shows the three-dimensional relationship between equipment parts.

302.283

Figure 6-24.—A starboard-bow view of the Soviet-guided missile cruiser *Slava*.

INTELLIGENCE PHOTOGRAPHY

The purpose of intelligence or reconnaissance photography is to gain information about an enemy or potential enemy. Now that the Soviet Union has been disestablished, the Russian threat to our national security has been greatly reduced. This does not suggest that intelligence photography is no longer required, but that our focus on other threats has intensified. Whether it be interdiction of drug smuggling operations from South or Central America or the potential nuclear threat of a third world nation, the need for intelligence photography will always exist.

Many people think intelligence photographs are always taken with highly sophisticated equipment from an aerial or satellite platform. While it is true that a great portion of intelligence is gathered through these means, much information can be gathered at ground or sea level. In this training manual, aerial collection of information is not addressed. However, intelligence photography

from ships or shore, specifically the photography of ships, aircraft, and ports is discussed (fig. 6-24).

When you are shooting photographs for intelligence purposes, high-quality and sharp image definition is of utmost importance. Black-and-white film is primarily used for intelligence photography due to its finer grain and higher resolution than color film. Whenever possible, black-and-white and color film, as well as motion video, should be used to document subjects of interest for intelligence purposes. The best black-and-white film for this purpose is Kodak Technical Pan (Tech Pan 2415), because of its ultra-fine grain and extremely high resolving power. For color intelligence photographs, you should use Kodak Ektar films, because of their fine grain, higher sharpness, and the variety of speeds available (ISO 25, 125, 1000); they also have the ability to produce high-quality enlargements. Although the resolution of video is inferior to that of film, the ability to view video instantly is advantageous for subjects of special interest.

SHIPS

When assigned to provide photographic coverage of a ship for intelligence collection purposes, you should attempt to provide as much information about the subject as possible. The standard nine-point coverage assists in providing this information in a photograph. The standard-nine points are as follows:

1. Bow
2. Starboard bow
3. Starboard beam
4. Starboard quarter
5. Stem
6. Port quarter
7. Port beam
8. Port bow
9. Vertical

The two most important shots are the starboard beam and the port beam. These two angles are most helpful to analysts for determining the overall dimensions of the ship.

High-angle photographs, such as from a crane, tower, or superstructure, are desired whenever possible. Closeup photographs taken with telephoto lenses are also important to support the basic nine-point coverage. You should photograph the following items (in priority order):

1. Over-the-side equipment and buoys
2. Missiles and launchers
3. Radars
4. Antennas
5. Sonar domes
6. Sensor protrudents
7. Helicopters (on deck and in flight)
8. Unusual optical or electro-optical devices
9. Unusual activity
10. Guns
11. Superstructure
12. Cranes, masts, and booms
13. Ports, hatches, and openings

14. Appendages and fittings
15. Identification numbers, flags, and markings
16. Oceanographic deck equipment

It is good practice to overlap your coverage when shooting with a telephoto lens. This will aid in determining the working relationships between components as well as providing the largest image possible on the negative or videotape. Photographs that provide information pertaining to cargo, personnel count, and bridge or electronic detail may be invaluable. It is better to overshoot than not to cover an area that may provide critical information about the subject.

More times than not, the lighting conditions are very poor when shooting photographs for intelligence purposes. Remember, the exposure latitude for Tech Pan film is very short, so your camera exposure is critical. You will be shooting into shadow areas and open hatches, so bracket all your frames to ensure you record detail.

When a submarine is the target of special interest, closeup views of the following equipment is useful for intelligence gathering:

1. Armament installations
2. Electronic installations
3. Sail area
4. Telescoping equipment
5. Unusual sensor probes and devices, such as trailing wires
6. Unusual, unidentified, or modified equipment

If you are photographing equipment, cargo, or written material that is recovered from floating wreckage of a ship, you should include a ruler in the photograph to show a scale as to the size of the object. The use of a macro lens will be needed to photograph nameplate data, writing, or markings on the recovered material.

AIRCRAFT

Photographs can provide valuable information about the capabilities, mission, and useful range of an aircraft. Whether the aircraft is in the air or on the ground, the way you photograph it aids the analysts in

PH2 K. Brewer
302.284

Figure 6-25.—The Soviet cargo ship *Nbah Pycakob* in the port of Conakry, Guinea.

determining these factors. The basic requirements for photographic coverage are as follows:

1. Overlapping views of the port side, the starboard side, and the underside, including wings and wing tips
2. Radome and appendages
3. Antennas
4. Fuselage area under the horizontal stabilizers
5. Upper section fuselage
6. Odd-colored covering on the skin of the aircraft
7. Bomb bay areas, especially if open
8. Other open hatches
9. Landing gear
10. Engines and cockpit
11. Identification markings

12. Weapons

When shooting aircraft, the underside of the aircraft is almost always in shadow. Remember to compensate for your light meter reading, particularly when the aircraft is airborne. Use the substitution method of exposure to record an acceptable exposure.

PORT

There are times when the ship may pull into a port that has not been visited by Americans for quite some time (fig. 6-25). Photographs can provide a wealth of information such as trading, harbor depth, and various other activities and capabilities of a port. You may be tasked to provide photographic coverage. The following areas should be documented:

1. Panorama of port
2. Ships in port
3. Channel markers

4. Piers
5. Cranes
6. Warehouses
7. Railheads
8. Fuel farms

9. Port headquarters building
10. Dry docks
11. Ship repair or ship building yards

Most photographs of a port can be taken when your ship is entering or leaving the harbor. Never sneak around military installations or restricted areas in any port.

CHAPTER 7

PORTRAITURE

A portrait is a likeness of a person, especially the face. This definition isolates *one* essential point in portraiture. A portrait should emphasize the person, rather than the person's environment or something associated with the person. However, a pictorial representation that portrays *only* a recognizable likeness of a person is not enough. A portrait must be more than just a photograph. It must have mood, personality, and possess characteristics from which a viewer can draw conclusions about the subject. By manipulating expressions, posing, lighting, and environments, a portrait photographer can portray any mood from happiness to gloom, as well as the personality of a subject. Posing the subject with familiar objects and environments can produce a more natural expression and pose because the subject will be more at ease. Articles or props included in the scene can help tell more about the subject.

Success in portraiture requires a thorough understanding of the techniques involved, an artistic ability, and a talent for directing the subject through a desired expression or pose. The portrait photographer should have a sensitivity for, and an understanding of, people. Portrait photographers vary considerably in their styles and techniques. The subjects of portraits vary in their likes and dislikes. There is no one blueprint or formula that will assure success.

The portrait is an interesting and challenging assignment to many Navy photographers. In portraiture the subject is always changing and challenging the Photographer's Mates. To meet the challenge of portrait photography, you must have vision, good judgment, and the ability and willingness to show them to greatest advantage.

Most people have their portrait made because they want someone else to see how they look. A beautiful woman knows she is beautiful, and in a picture, she wants to appear beautiful-so make her beautiful. Some flattery may be necessary, but you should not overdo it. Men know their features; they know whether they appear dignified; they know whether they appear to have great strength of character; and they are correct in expecting the photographer to emphasize these good points. The subject expects a true portrait-a good expression and a natural pose, a portrait that shows

whatever beauty or strength the person has, and one that reflects his or her character and features.

Character is formed by life. A frown or a smile today leaves no trace, but continued use of facial muscles to form a smile, a laugh, or a frown leaves lines on the forehead, around the eyes, nose, and mouth. These lines and expressions form facial character. They are subdued or exaggerated by the way you light the subject. You should not eliminate character lines altogether, but, you should only soften them with lighting. A face has features: two eyes, a nose, a mouth, and two ears, but photographically these features are not equally important. To the portrait photographer, the most important and most expressive are the eyes; the mouth is second only to the eyes.

Facial expressions constantly change and last only momentarily. No happy expression or frown lasts long enough to take full notice of it-until it is photographed. When you photograph an expression at the wrong instant, all the bad points appear exaggerated.

To be a good portrait photographer, you must learn to study each face as it appears before the camera, and light it to represent the natural features and character accurately. Do not try to capture that fleeting expression. It is not the expression that shows that person's true character. What you want is a person's natural expression. A softness of expression is best-neither too sharp nor too faint; not too lively or too gloomy.

PORTRAIT STUDIO

The portrait studio should be a place isolated from distraction where the photographer and subject can work without interruption. It should be a comfortable place where the subject feels at ease, where the *tested* equipment works, where the color quality of the light can be controlled, and where the photographer and subject can move from pose to pose without interruption. Avoid using the portrait studio as a crew's lounge or lunchroom. The portrait studio should always be clean and neat. The portrait studio is one of the few areas that customers ever see, and it represents the overall condition of your photo lab.

The studio should be arranged so the lights, camera, and electrical cords are safely out of the way and your subject does not have to avoid tripping over them. Every effort must be made to make the portrait session a pleasant experience for the customer. Any props to be used should be stored out of the way where they can be retrieved quickly and easily.

The studio should be spacious enough to move around freely, with enough room surrounding the posing bench so the subject does not feel crowded. The distance from the posing bench to the background should be great enough so shadows from the subject are not cast onto the background. This distance should also be great enough so the background is out of focus when the lens is stopped down to the working aperture. The studio should have enough room so a longer than normal lens can be used and provide enough room behind the camera so the photographer can move about freely. It should be wide enough so the lights can be moved in an arc around the subject without changing the light-to-subject distance. The ceiling should be high enough to provide enough space for a standing full-length portrait.

Whatever the size or location of the studio, it must, above all, be a productive, professional workplace, having everything required to produce technically perfect portraits.

In many Navy photo labs, especially the old ones and aboard ship, these conditions do not exist. Just because you do not have a large "professional" studio and equipment does not mean you cannot produce professional quality portraits. Many professional quality portraits are made by Navy Photographer's Mates using only two small lights in a compartment being used as an office, finishing room, and darkroom aboard ship.

STUDIO EQUIPMENT

There are endless types and manufacturers of studio equipment available for controlling light and making portraits. The size and the budget of your imaging facility determines what is available for making portraits. This chapter discusses only the basic studio equipment that is common to most Navy imaging facilities.

Camera

Regardless of what camera you use in the portrait studio, it should be clean and in good working order. The

camera should have interchangeable lenses and be at least medium format. The larger the negative size of your portraits, the higher the quality of the finished product.

Lenses

A lens used for portraits should have a longer than normal focal length. A long-focal-length lens produces a large image on the film while keeping the camera at a far enough distance from the subject to prevent image distortion. Normal-focal-length lenses are too short for anything but full-length portrait photography. They require the camera to be too close to the subject, image distortion becomes apparent, and working too close to the subject may intimidate him or her. Working too far from the subject with a normal lens to prevent distortion makes the image size too small. The ideal lens for portraiture should have a focal length equal to 1 1/2 or 2 times the diagonal of the film. When you are using 4x5 film, the lens focal length should be about 8 to 12 inches.

Background

Simplicity is the key word in portrait backgrounds. Simple backgrounds give more artistic results by maintaining viewer interest on the subject. The most widely accepted background is a large, flat, unmarked surface, such as a painted screen, an actual wall of the studio, or seamless background paper suspended from the ceiling. Whatever the background, it should have a matte finish, rather than a glossy finish. A glossy finish causes distracting reflections.

A background can be plain or patterned. When the background has a pattern, it must not detract the viewer from the main subject. When props are used, such as a globe or an American or Navy flag, they must not draw attention away from the subject.

The background should normally be light and neutral in color; however, black or dark backgrounds are used for certain effects. A black background is used to add richness to the finished print. When a black background is used, keep your subject a good distance from it to prevent the lights (except the background light) from striking it.

The color of a background becomes important when color portraits are made. Bright-colored backgrounds should be avoided because they distract from the subject. When using a cold-colored (blue, green, etc.)

background, you must prevent the background from reflecting colored light onto the sides of the subject's face. This produces a sickly appearance. The background tone can be changed by adjusting the amount of light falling upon it. Dark backgrounds with earthen colors, such as brown and dark orange, can be used for low-key portraits. Intensely illuminated backgrounds with light pastel colors can be used for high-key portraits.

Your studio should have enough backgrounds to meet the demands of customers. As a minimum, you should have a gray or light blue background for roster photographs and white for full-length photographs. Always stock extra white seamless paper. White seamless paper is used mostly for full-length photographs. This paper becomes dirty and is torn rapidly since it is being continually walked on. You can extend the life of the background paper for full-length portraits by laying sheets of acetate (such as clean-up film) on top of the area to be walked on. The acetate does not show up on the film or print.

Lights and Accessories

Almost any type of light can be used for portrait photography. This includes natural light, such as the sun, as well as artificial light, such as electronic flash.

The sun, with its different forms of illumination—daylight, skylight, and window light—is the major source of natural illumination for portraits. The sun is used primarily for location portraiture.

Most types of artificial light can be used for portrait photography as long as the intensity is sufficient to permit short exposures. Short exposures are desired because it is difficult to keep a subject motionless during a long exposure. For color portraits, the color quality of the light source should be the same as that for which the film is balanced. Of all the artificial light sources available, electronic flash is the best light source for portrait photography because of the following:

- It provides a large output of light without the annoying heat produced by incandescent lights.
- The extremely short duration of the flash stops subject movement.
- The color temperature of the light is compatible with daylight.
- They are as versatile as other light sources.

Electronic flash units specifically designed for portraiture usually have tungsten modeling lamps located near the electronic flashtube. These modeling lamps provide constant, low-intensity illumination on the subject or background. This allows you to see the lighting effect that will be produced when the electronic flash units are fired.

BASIC LIGHTING UNITS.—Studio electronic flash units are divided into two broad classifications: those that project a relatively narrow cone of concentrated, crisp light and those that project a broad area of softer, more diffuse light.

Spotlight.—A spotlight projects a narrow, highly concentrated, crisp beam of light, produced by an undiffused clear flashtube. A Fresnel lens or a small reflector with a mirror finish is used to direct and focus the light. The light produced by a spotlight is very much like direct sunlight on a clear day. The light rays are nearly parallel and are not diffused. The shadows cast by a spotlight are hard with sharply defined edges that add crispness. A spotlight is usually used to highlight or stress a feature of the subject or as a hair light or background light.

Floodlight.—A floodlight produces a broad area of partially diffused, soft light, very much like sunlight on an overcast day. A frosted globe is used over the flashtube, so the light produced is initially diffused. The light is further diffused by the reflector that causes the light rays to cross and interfere with each other. The rays, projected from the front of the flashtube, however, are not as diffused and have a crisper quality. The light, produced by an electronic flash floodlight, has a crisp quality at the center and a softer quality toward the edge. When you want to use just the softer part of the light, allow only the outer part of the light beam to fall on the subject. This technique is called *feathering* the light. When you want the entire beam of light to be diffused and very soft, use a diffusing screen over the light source. There is also a type of light unit known as a *capped* light. This type of unit has an opaque metal cap placed in front of the flashtube to block specular light from reaching the subject. All light projected by a capped unit is diffused.

A floodlight is usually used as the main (modeling, or key) light in portraits, especially where a soft effect is desired. It is also used as a fill light because a fill light is always diffused.

ACCESSORIES.—Many accessories are available for use with studio lighting units. Accessories are

important tools that make your portrait lighting units either more dependable or more versatile. They aid in creating the exact lighting affect you want. Common accessories are as follows: diffusers, barn doors, snoots, and umbrellas. If accessories are not available, compromises in the lighting can alter the effect and quality you desire.

Diffusers.—You use diffusers when you want to change specular light to a softer, more diffused light. Diffusers are made of translucent or mesh materials that, when placed in the light beam, break up or diffuse and soften the light. The finer the mesh, the more diffused the light. When only a small amount of diffusion is needed, a wide mesh material, such as *gray* window screen, works well. For more diffusion, two pieces of screen can be placed together slightly out of alignment, or a finer mesh material, such as *white* cheesecloth, can be used. Floodlights initially produce a fairly diffused light, but diffusers may also be used with them. Diffusers can be mounted on the light unit or placed somewhere between the light unit and your subject.

There are many reasons for using a diffuser instead of a light that already produces diffused light. A diffuser may be needed when you do not have a soft light available. A softness that is between two different light sources may be needed, or you may want to produce a small area of diffused light that can only come from a spotlight with an installed diffuser.

Barn Doors.—Barn doors are made from opaque material. They are usually made of metal, painted black, and attached and hinged to the front of a light unit. They can be positioned to block or feather a portion of the light produced by the unit. Barn doors are made for both spotlights and floodlights. They are good accessories for controlling spill light.

Snoots.—Snoots are cylinders, open at both ends, usually made of metal and painted black. They are used at the front of a spotlight to limit the size of the circular area projected by the unit. Short, wide snoots give a large circle of light. Long, narrow snoots give a narrow circle of light. A cardboard tube or black-rolled paper can be used for a snoot when you need to improvise.

Umbrellas.—Umbrellas work much like the reflectors used on floodlights and provide an excellent means of converting specular light into soft, diffused light. They are used with any light source. The light unit is pointed away from the subject; the umbrella is

attached in front of the light and reflects or bounces the light back and onto the subject. The reflected light falling on the subject is softer and more diffused than the light originally emitted by the source.

The reflecting surface of the umbrella determines the quality of the light. Umbrellas are usually made with a matte, white surface that provides a very soft, completely diffused light. Some umbrellas are constructed with a shiny, metalized surface. Metalized umbrellas throw a somewhat specular light, but the light is softer and spread over a larger area than the light emitted by the original light source.

FILM FOR PORTRAITS

For black-and-white portraits, black-and-white panchromatic film is generally used. With a pan film, the appearance of any red spots, veins, or redness in the subject's skin is apparently reduced in the final print, because of the sensitivity of the film to red. Conversely, an orthochromatic film can be used when the texture of a man's skin, especially an older man, is to be emphasized.

When you select a color film for portrait photography, there are two important considerations: What type of product is to be produced and what is the color of the light source?

Another factor to consider in selecting a film for portraiture is the ISO film speed in relation to the intensity of the light source. A slow film can be used successfully with a light source that has relatively high intensity, such as an electronic flash unit. When the same slow film is used with a light source that has relatively low intensity, an extremely wide aperture must be used. When a fast film is used with a high-intensity light source, a smaller aperture is required, increasing the depth of field which may not be desirable for portraiture.

When you are shooting portraits, do not be stingy with film. With a medium-format camera, you have 9 to 15 frames to work with. When you have the commanding officer or the admiral in the studio for a portrait, shoot at least the entire roll. Never shoot just three or four frames. Film is cheap and you want to provide the customer with a variety of poses and expressions to choose from.

MAKING THE APPOINTMENT

When possible, portrait times should be made by appointment. Using an appointment system gives you a

good start towards making a successful portrait. By using an appointment system, it tells your subject that he or she is important and will not be wasting time waiting to get into the studio. This brings the person to the studio with a positive attitude, and that is half the battle. An appointment also helps you. When an appointment system is used, you know how much time you have to work with each subject, and you do not have to rush through a sitting because someone else is waiting prematurely. Between appointments you have time to straighten up the studio, load film, complete job orders, screen processed portrait film, and so on.

Appointments should be made at least 15 minutes apart. This way you have time to take care of other business that may come up. If one customer is a few minutes late, you can also use this time to catch up.

When appointments are made, suggest to the person that they come in early in the day. Most people look their best and their clothes are fresher early in the day. Men, particularly those who develop a heavy beard (five-o'clock shadow), need to have their portraits made at the beginning of the day. However, they should not shave then come right in to be photographed. This provides time for facial blemishes, caused by shaving, to disappear.

Men should have a haircut and look sharp, but the haircut should be a day or two old. Uniforms should be pressed and well fitted with all awards, grade, and rating insignia properly placed. A chart of military awards and decorations is helpful in settling differences regarding the proper placement of ribbons and metals.

THE SUBJECT

When someone comes to the photo lab for a portrait, that person usually feels uncomfortable (like going to the dentist). Your attitude can help make the person feel relaxed. The secret to your success in putting the subject at ease is to convey a genuine and sincere attitude. Let the person know by your words and actions that you plan to do your best to produce a portrait that anyone would be proud to display.

Your attitude will leave a lasting impression on the subject and set the tone for the portrait setting. Greet the customer warmly, with a smile on your face as well as in your voice.

You, as the portrait photographer, should make it your business to know something about the subject. What is his job? Where does she work? How long has

he been on board? What was her last duty station, and so on? The more you know about your subjects, the easier it is to work with them. Train yourself to gather a quick impression of the subject's intellect, taste, and aspirations. Talk to each of them and gather information regarding their special interests.

Conversation sooner or later strikes a responsive chord and the subject's face comes to life and gives you that natural expression so necessary to the finished portrait. Since the success of the portrait depends greatly on a natural expression, your task is to create a friendly situation whereby the subject feels he has an equal part. The making of a good portrait depends on cooperation. Do not rush a sitting and avoid getting flustered. You must always control the situation.

Invite your subject into the studio in a casual way. Have a bright light on, usually the main or modeling light. This way the shock of turning on a bright light in a dark studio is avoided. Ask the subject to be seated; a motion with your hand may be enough. A person who is treated in a friendly yet respectful manner, and kept in casual conversation, usually strikes a natural pose better than one who is not. If this fails, you must skillfully direct the subject. At times you may have to touch the subject to adjust a hat, sleeve, necktie, coat, and so on. Before touching the subject, explain to the person what action you are about to take.

Talk to your subject and direct movements, from in front of the camera, within the circle of light. It is disturbing for the subject to hear a voice from a dark void trying to direct his or her movements.

Posing is the most unpredictable part of a portrait session. The subject is at a mental disadvantage because he has to follow your directions. This requires subtle handling on your part and an understanding of human behavior.

CAMERA HEIGHT

The best average camera height for a head-and-shoulders type of portrait is slightly above the subject's eye level. This places the subject's eyes well above the center of the picture space. Slightly above eye level then is a good place to start. Most portraits are made from this camera viewpoint, but individual features and characters of the subject often dictate a higher or lower camera position.

For three-quarter portraits, either sitting or standing, the camera height may need to be changed. For example,

Figure 7-1.—Subject looking directly into the camera.

you may want to start with the camera level at the upper chest or even at the eye level of the subject. Other factors that should be considered when selecting the camera height (especially with a head-and-shoulder portrait) include the shape of the subject's face and facial features, such as a long nose and the length of the subject's neck. By changing the height of the camera in relation to the subject, you can make corrections to emphasize or de-emphasize features of the subject.

For full-length portraits, you should start with the camera height about waist level and the lens parallel to the subject. When the camera height is too high or too low and the camera lens is tilted, distortion of the subject occurs. When the camera is too low, the subject's feet appear large and the head small. When the camera is too high, the subject's head and upper body appear large and top heavy.

A camera position below the eye level of a subject can produce a side effect that may be distracting; that is, showing the nostrils more prominently and causing them to appear as two black holes. To help remedy this situation, you should place the modeling light higher to cast a shadow beneath the nose, so the nostrils appear to blend in with the shadow area.

Figure 7-2.—Subject looking too far away from the camera.

POSING

The posing bench should be set at an angle to the camera. When the bench is square to the camera, people tend to sit on it with their shoulders square to the camera. This puts their shoulders straight across the picture and such a pose exaggerates the width of the shoulders. This pose is obviously inappropriate for a woman. When your subject is a male dignitary (VIP), a pose like this enhances those qualities. Very few people have positions that demand such a pose. Having the posing bench at an angle to the camera before the sitter arrives should automatically suggest to the subjects that they sit with their shoulders turned slightly from the camera. With the shoulders turned slightly from the camera and the head turned back toward the camera, a sense of motion is created. Even more motion and alertness can be suggested by having the subject lean slightly forward.

Eye Direction

To create an intimate portrait, the subject appears to return a glance to the viewer. The subject's eyes should look near the camera lens (just above or to the side of it). When the subject looks directly into the lens, a stare

Figure 7-3.—Rule of thirds.

will result (fig. 7-1). When the eyes are looking too far away from the camera, a vague, faraway look results (fig. 7-2). The eyes also lose their brilliance and sparkle, and too much white shows when the subject's eyes are looking away from the camera.

Portrait Composition and Subject Placement

As in every type of photography, in portraiture there must be one, and only one, principal point of interest. Naturally, in a portrait, this is the subject's face. You can emphasize the point of interest in a portrait by doing the following:

- Having it contrast with the background
- Giving it the strongest lighting
- Posing the subject and arranging the props so all elements point to it
- Locating it at a strong point within the picture area

Where are the strong points within a portrait picture space? The *principle of thirds*, as discussed in chapter 5, applies to portraiture as well. These are the areas within a portrait that attract eye attention and are the preferred locations for the center of interest (fig. 7-3). In a portrait, when the main point of interest is located at Point A, the secondary point of interest should be at Point D. If B is the point of interest, C becomes the

302.159

Figure 7-4.—Subject placed too high in the photograph.

secondary interest point. Such an arrangement obviously balances the composition.

As stated earlier, the subject's face is the point of interest in a portrait and, of course, covers a considerable area in the picture space. Usually in portrait composition, the eyes fall close to Points A or B. But these positions are approximations only. The final adjustment of the head depends upon several factors: the eye direction, the shape of the body, and the leading lines. No rule can be given for best portrait composition. Rules only give guidance to a rough approximation of good placement. You can only arrive at the best composition for each portrait through the feeling for balance and subject position.

When the head and shoulders are placed high in the picture frame, a sense of dignity and stability is gained. Such placement is particularly appropriate when the subject is a person of importance, such as the CO. However, when the head is too high (fig. 7-4), viewing the picture is uncomfortable because there is a feeling that if the subject stood up he would bump his head. Also, when the head is too high, the proportion between head and body areas becomes awkward.

302.159.1

Figure 7-5.—Subject placed too low in the photograph.

Most inexperienced photographers place the head too low, rather than too high. This is usually the result of the photographer's desire to show as large a head as possible. When the head is too low, there is not enough body to support it (fig. 7-5).

When the head is turned toward the side, avoid having the tip of the nose from coinciding with the outline of the cheek or projecting only slightly beyond the cheek line. In either case, the far eye will be divided by the nose. When the tip of the nose sticks out only a little beyond the cheek line, it appears as a lump on the cheek.

Before you seat a subject, suggest that the subject may like to check his or her appearance in a mirror. Combing the hair, straightening a tie, setting a hat at the proper angle, and smoothing out the lay of the clothes should ensure a neat, well-groomed appearance. When the subject is in military uniform, be sure that medals, ribbons, insignia of grade or rate, and other accessories are worn properly. These minor details are easily overlooked and failure to correct a discrepancy may make it necessary to retake the portrait.

When a military subject is seated, one particularly important point to consider is the lay of the coat collar. The collar has a tendency to separate from the back of

the subject's neck and project outward resulting in the impression of a hump. The coat should be pulled down to make the collar fit properly and make the line of the subject's back appear free from slouch or slump. When the portrait includes only the head and shoulders, the drape of the coat can be improved by unbuttoning the lower button and pulling the bottom of the coat down.

The sleeves of a coat are another problem, particularly when you photograph a seated subject. There is a tendency for the sleeves to work up and wrinkle at the elbows, allowing either too much wrist or too much shirt cuff to show. To help remedy this, have the subject pull the sleeves of the coat down and straighten out the wrinkles as much as possible. Wrinkles, folds, and unwanted creases in a uniform detract from a neat appearance. When the subject is wearing a long-sleeved shirt under a coat and the hands will appear in the portrait, both shirt cuffs should be visible or both should be out of sight. Do not have one cuff visible and the other not.

Stay near the camera and tell the subject what to do. You are obligated to give directions regarding the pose. A subject is not able to see all posing aspects for the portrait. Whether the subject is an admiral or seaman, you are expected to detect and correct any discrepancy in pose, uniform, gestures, or actions, and so on. One of the greatest obstacles to successful portraiture is the timidity of some photographers and the way they handle the subject. Never take a portrait when something about the portrait is wrong because of fear or timidity to speak and act in the presence of high grade. The results will be disappointing and embarrassing.

When the military subject is to be photographed uncovered, be sure that the hat is removed far enough in advance so any impression on the forehead caused by the hatband has time to disappear.

When the subject shows a tendency to squint or blink, suggest that he rest his eyes by closing them for a moment. The facial expression is an important element to a good portrait. Unless some method is used to induce a pleasant expression, the subject will generally appear bored and uninteresting. Telling a subject to look this way or smile is not enough to cause the subject to smile. A forced smile sometimes looks more like a frown. A good method to get a pleasant expression is through conversation. Talk about a recent incident, a funny story, the weather, or any other topic that will cause the subject to concentrate on something other than the business of making a portrait. With most people, a smile is contagious. When you smile at a person, the person usually responds with a smile. Beware of a broad smile

because it rarely looks attractive, and it is usually not appropriate for a person in a military uniform. While you are trying to induce the expression that will show off the subject to the best advantage, be particularly observant of the details necessary to maintain a neat appearance and good composition.

FUNDAMENTAL PORTRAIT LIGHTING

The success of a portrait is equally dependent on lighting as on the pose of the subject. The manner in how the subject is lighted can actually set the mood of a portrait. The best portrait lighting will simulate natural sunlight. This is because we are accustomed to seeing faces illuminated from above and to one side with shadows cast downward and on one side or the other. Light coming from below eye level casts shadows upward and produces an unnatural, ghastly effect. Good portrait lighting shows off the subject to the best advantage, emphasizing the form and expressiveness of the facial features. When lighting appears pleasing and natural in a portrait, it produces prominent highlights on the forehead, nose, cheeks, and chin with enough shadows to round out the facial features.

Lighting for a studio portrait normally requires at least two lights. One of these is the *main*, *modeling*, or *key* light; the other is the *fill* or *fill-in* light.

Portrait lighting is divided into various types called lightings. Some of these lightings are as follows: broad, short, butterfly, Rembrandt, split, and rim. These names have been assigned because of the visual effects the lighting creates when it falls on the subject from a given direction. This visual effect is derived from the modeling light. Other light sources that may be added to the *modeling light* to enhance the subject are as follows:

- Broad lighting—The main light completely illuminates the side of the face turned toward the camera.
- Short lighting—The main light completely illuminates the side of the face turned away from the camera
- ◆ Butterfly lighting—The main light is placed directly in front of the face and casts a shadow directly under the nose.
- Rembrandt lighting—This is a combination of short and butterfly lighting. The main light is placed high and to the side of the face turned away from the

camera and produces a triangle of light on the side of the face in shadow.

- ◆ Split lighting—The modeling light is placed to light completely one side of the face while placing the other side of the face in shadow.

- ◆ Rim lighting—The modeling light is placed behind the subject and places the entire face in shadow.

MAIN LIGHT

The main light is often called the *modeling* light because it is used to model the face (or subject). The main light creates a three-dimensional effect by either emphasizing or de-emphasizing the curvature and characteristic features of the face with highlights and shadows. The modeling light should always be the one dominant light source in a portrait because it controls the direction of the shadows.

The direction of the main light establishes four basic portrait lightings. These basic lightings are as follows: *three-quarter lighting*, *side lighting*, *frontlighting*, and *backlighting*. When reading other books on portrait lighting, you will often encounter other names depending on what the author wanted to call the lightings. You, as a Navy Photographer's Mate, will mostly be concerned with three-quarter (broad and short) and front (butterfly) lighting.

We also designate each of our lightings as high, medium, and low for vertical position. To go further, we designate the lighting as right or left of the subject.

These lighting positions change with each subject. When setting portrait lights, you should always study the effect and view the subject from the camera position, preferably through the viewfinder.

THREE-QUARTER LIGHTING

Broad and short lighting are two types of three-quarter lighting, and they are the types that you most often use for official portraits. The only difference between the two is the position of the main light and the way it illuminates the subject.

Short lighting is used for people with a normal shaped face or people who have a wide face. When short lighting is used, the side of the subject's face that is away from the camera is illuminated. This puts the side of the face towards the camera in shadow. By putting the side of the face towards the camera in shadow, you can provide a slimming effect.

SHORT LIGHTING
MAIN LIGHT ONLY

SHORT LIGHTING

BROAD LIGHTING
MAIN LIGHT ONLY

BROAD LIGHTING
WITH FILL LIGHT

PH1 Casey Akins
302.310

Figure 7-6.—Broad and short lighting.

Broad lighting is useful for subjects with a narrow face. When broad lighting is used, the side of the face towards the camera is illuminated, and the side of the face away from the camera is in shadow. This provides a widening or broadening effect of the face. Refer to figure 7-6 to compare the differences of short and broad lighting.

Main Light Distance

The power or intensity of the main light is not the determining factor for the distance the main light is placed from the subject. It is the visual effect the light has on the subject that determines this distance. When the main light is too high and close to the subject, there

may be too much light falling on the forehead and not enough light falling on the lower part of the face. This effect can be improved by moving the main light farther away from the subject and placing it correctly.

Highlights on the forehead, the upper cheeks, the chin, and along the bridge of the nose are created by the main light. These highlights give life, brilliance, and form to a portrait, and the quality of these highlights are controlled by the main light distance.

To determine the main light distance, start with the light about 4 feet from the subject and about 2 feet above the subject's eye level. The light should be about a 45-degree angle to the lens axis. Observe the forehead highlight and move the light closer to the subject; as the light gets closer to the forehead, highlights spread out to a large, flat area and begin to wash out.

Now, start moving the main light away from the subject. As you slowly move it back, you will find there is a point where the forehead highlight becomes relatively small and bright. When the light is moved back much further from this point, the highlight spreads and disappears. Between the point where the highlight is brightest and where it starts to disappear lies the range where the highlight still has character. This point is where you get the most pleasing effect. Once you have found the distance where the main light gives your desired effect, the *distance* should remain the same regardless of the *direction* you need to move the light. This main light distance should always be considered as the *starting* point of portrait lighting.

Main Light Height

To determine the correct height for the main light, move the light directly in front of the subject while maintaining the distance determined for the forehead highlight. Raise or lower the light until the shadow cast by the nose is just long enough to touch the top edge of the upper lip. This is the height the main light should normally be no matter at what position you place it in an arc around the subject.

When your subject is wearing a hat with a visor, the visor shadow should fall naturally across the face. Many photographers think the shadow cast by the visor should not shade the eyes. The shadow from the visor *should* shade the eyes, however, in a portrait, this shadow should not be so dark that shadow detail is lost and the eyes are hard to see. To prevent this shadow from being too dark, raise the main light to the desired height, and instead of aiming it down at an angle, aim it straight.

This way the light is cast under the visor and prevents the shadow from becoming too dark

Main Light Direction

By the time you have determined the main light distance and the height for a given subject, you should have a pretty fair idea of the direction you want the main light to come from. To establish the direction from which this light should come, move the main light in an arc, to the right or left, around the subject. Remember, while moving the main light, its established distance and height should be maintained.

The shadow cast by the subject's nose is your key to main light direction. The light should be moved around until the shadow cast by the nose merges with the cheek shadow and leaves a small, triangular highlight on the cheek. When this is done, the main light is in position. Remember, the main light must always be the dominant, directional, shadow pattern forming light.

Fill-in Light

Once the main light has been established, the fill or fill-in light is added. This fill light is a secondary light and must not overpower the main light. Its purpose is to fill in and soften the shadow areas, making them lighter, and to provide shadow detail.

The fill light is normally placed slightly above the subject's eye level, on the opposite side of the camera from the main light and near the camera lens axis. The fill-in light should be less intense than the main light and of softer quality. This light is often diffused even when the main light is not.

By placing the fill light slightly above the subject's eye level, you can cast a shadow under the chin. This shadow separates the head from the neck. The chin shadow should be soft and unpronounced.

The intensity of the fill-in light can be controlled by either adjusting the power setting of an electronic studio light set or adjusting the light-to-subject distance. The fill light can be moved in an arc to the side of the subject and away from the camera. The fill light must not produce conflicting shadows (shadows that point toward the main light).

Catch Light

There should be a small, bright reflection of the main light in the eyes of the subject. This is a catch light. The catch light adds life and brilliance to a portrait and

PHC Carl Hinkle
302.311

Figure 7-7.—Effect of background light.

gives the eyes sparkle. There should be only one catch light in each eye, and it should be high in the iris of the eye. For broad lighting, the catch light should be approximately in the 11 o'clock position. The main light for short lighting should create a catch light at approximately the 1 o'clock position.

Lighting Ratio

The lighting ratio for portraits should usually be about 3:1 or 4:1-3:1 is about maximum for good color portraits. To refresh your memory on how to establish lighting ratios, refer to chapter 5.

Background Light

The third light in studio portrait lighting is the background light. A background light is usually placed on a low stand midway between the background and the subject. When adjusted correctly, the background light provides good tonal separation between subject and background. The intensity of the light falling on the background should not normally be greater than the intensity of the light from the main light falling on the

subject's face. By increasing or decreasing the intensity of the light on the background, you can control the tone or color reproduction of the background in the finished print.

To reproduce the background color to its "true" color in a color print, it must receive the same amount of light as the subject's face. When taking portraits for use on a roster board, you want the tone and color of the background to be consistent. When the backgrounds vary in color, the roster board does not appear uniform, and the attention of the viewer is distracted.

When a background light is used, it is wise to position it before setting up any other light. It is easier to determine its effect without the interference of the main and fill light. The background light should be positioned so the brightest area of the light illuminates the background directly behind the head and gradually falls off into the corners of the frame (fig. 7-7). When the background light is set in this manner, it separates the head from the body and draws the viewer's attention to the subject's face.

Hair Light

Once the main, fill, and background lighting is established, additional lights may be added to the setup. One such light is a hair light. A hair light is usually a small lighting unit placed on a boom so it shines down from above and behind the subject. It is used to lighten the hair (or hat) and shoulders, add detail to the hair, and separate the subject from the background, presenting the illusion of a third dimension (fig. 7-8).

The intensity of the hair light varies with the subject since it is dictated not only by the color of the person's hair (or hat) but also by the amount of sheen the hair has.

The hair light is usually placed on the side of the subject opposite the main light and behind the subject. It should be used from an angle about 6 to 8 feet high and from a position close to the center of the subject area without the light stand or boom showing in the picture. Light from this unit should not be allowed to spill over onto the forehead or tip of the nose. The hair light normally has a snoot attached so light from it does not strike the camera lens.

Be sure the hair light is turned off when making any exposure readings. This light does not affect your basic film exposure, but it could influence your meter.

PHC Carl Hinkle
302.312

Figure 7-8.—Effects of hair light.

Flexibility of Three-Quarter Lighting

Three-quarter lighting can be used with almost any type of face. It is flexible because once it is set, the subject can move his head from full face to profile and the lighting remains good at any point you choose to pose the sitter. The degree of flexibility is determined by the type of light used (spot or flood) and the size and type of reflector used.

SIDE LIGHTING

With side lighting, the face is lit more intensely on one side than the other (fig. 7-9). This type of lighting is well suited for young women that have smooth skin and regular facial features, or for men whose rugged character lines should be emphasized. As a Navy Photographer's Mate, you will not normally use side lighting for official portraits. To learn more about side lighting, refer to the reference list in the back of this training manual.

BUTTERFLY LIGHTING

Butterfly lighting is often used when making portraits of women. To start, you can place the main light

PHC Carl Hinkle
302.313

Figure 7-9.—Side lighting.

PHC Carl Hinkle
302.314

Figure 7-10.–Butterfly lighting.

very close to the camera lens axis and about the subject's eye level. This creates a flat lighting, and facial feature characteristics can be lost. By moving the main light higher, you can create a certain amount of modeling. The light now creates a little modeling and is still very flattering and almost foolproof. This lighting is considered flattering because it does not emphasize lines or crowfeet around the eyes, wrinkles on the forehead, or shadows around the mouth. It does, however, emphasize eyes and eyelashes, especially in females.

The main light should be just high enough to cast a shadow of the nose about a third of the distance from the nose to the top edge of the upper lip (fig. 7-10). Each subject's face and nose is different, so the correct height for the main light varies slightly. When the subject has a long nose, the light should be low to shorten the shadow. When the subject has a short nose, raise the main light to lengthen the shadow. This has a secondary effect as well. It adds form below the eyebrow and accentuates any slight hollowness in the cheeks, giving a more provocative look.

When making a portrait of a person smiling, you must shorten the nose shadow because the upper lip draws up and the shadow goes over the lip. The nose

shadow should not extend over or touch the edge of the lip. When it does, the lip form is destroyed and it appears unnaturally small.

The main light-to-subject distance is again determined using the forehead highlight test.

The fill-in light is positioned directly below the main light-close to the camera lens axis and slightly above the subject's eye level. The intensity of this light should be about one f/stop less than the main light. The lighting ratio is established by moving the fill light closer to or farther away from the subject to increase or decrease its effect. Balance also can be controlled by using diffusion screens over the fill-in light.

Although not as flexible as three-quarter lighting, frontlighting does have some flexibility. The subject's head can be posed from full face to profile. However, the nose shadow must always remain under the nose. Therefore, the main light must be moved with the head; and as the head moves to the three-quarter or profile position, the hair light also must be moved. The fill light is not moved.

RIM LIGHTING

Rim lighting is often used when making profile portraits. Rim lighting is the same as backlighting, where the subject is lighted from behind causing the facial features of the profile to be highlighted (fig. 7-11). Some suggestions to use when taking profile portraits are as follows:

- In a profile portrait, when a person looks straight ahead, only the whites of the eyes are seen by the camera. This causes an undesirable effect. Instead have the eyes cheat-turn the eyes slightly toward the camera, without turning the head, to show enough of the iris so the eye can be seen as an eye, not a white ball.
- Have the subject's head tipped back slightly. This separates the chin from the far shoulder, gives a better neckline, and reduces the appearance of a double chin.
- Allow more space on the side of the picture toward which the eyes are looking. This allows the subject to "look" beyond the frame.

If you are interested in learning more about rim lighting, refer to the reference list in appendix III.

Figure 7-11.—Rim lighting.

FULL-LENGTH PHOTOGRAPHS

Officers of the Navy and Naval Reserve, in grades CWO3 through CWO-5, or O-3 through O-8, must submit a full-length photograph of themselves before being selected for promotion to the next higher rank. Other special selection boards require a full-length photograph to be included in the applicant's package, such as the limited duty officer program, Sailor of the Year, and other programs in which a selection board process is used. Candidates for officer promotion and LDO or CWO selection boards should refer to *NAVPERS Manual*, 15560C, and *NAVMILPERS-COMINST*, 1131.1A, respectively, for the most current information.

BACKGROUND

Since the studio setup is unique for full-length photographs, they should be scheduled at a time other than that of normal head-and-shoulders portraits. The background for full-length photographs must be a contrasting color from the uniform of the subject. Normally, white seamless paper is used because it provides the best results.

When white seamless paper is used for full-length portraits, it must drape down and provide enough coverage for the subject's head and extend to the deck so the subject is standing on it. You should protect the background from footprints and tears by laying down a protective material, such as paper or acetate.

302.316

Figure 7-12.—Full-length photograph.

LIGHTING

When lighting a full-length portrait, you must light the entire body of the subject evenly and not allow objectionable shadows to show on the final product. This is best achieved when the subject is lighted with light diffused from two umbrellas. The background can be evenly lighted with two background lights. You should always conduct tests to determine the best lighting setup for your studio equipment and facilities.

POSE AND COMPOSITION

The full-length officer portrait must be a three-quarter view with the left shoulder forward. For officer promotion photographs, the prescribed uniform is summer khakis (summer whites where summer khakis are not authorized) and dress blues for LDO or CWO applications. All subjects will be uncovered unless otherwise stated in the applicants appropriate instruction. A menu board or hand-lettered title board must be placed at the subjects feet and be legible in the final photograph. The subject should be

centered both horizontally and vertically in the photograph (fig. 7-12).

The best camera and film to use for a full-length photograph is a 4x5 camera and a Polaroid 4x5 film back. When this combination is used, the customer can leave the studio with the final product. Any camera or imaging system can be used, depending on your imaging facilities capabilities, providing that two 4x5-inch prints are furnished to the customer.

CORRECTIVE TECHNIQUES

The primary goal in portrait photography is to present the subject in a favorable and flattering manner. Your most difficult problem is combining the pose, lighting, and camera viewpoint to show your subject to

best advantage. Because the photogenic qualities of each person's face vary, certain corrective techniques in posing, lighting, and camera heights can be used to help depict the subject favorably and improve the quality of the portrait. Changing the camera viewpoint, combined with proper lighting and pose, can create amazing alterations in the pictured appearance of any face. Table 7-1 shows corrective techniques and ways they can be used to correct common problem areas.

EXPOSURE CALCULATION FOR STUDIO PORTRAITS

Normally, the exposure for portraits should be based on the fill light alone as measured at the subject position. The fill light is the single source of illumination to the shadow areas and image detail in the shadow areas.

Table 7-1.—Corrective Treatments

Problem	Treatment
Fat, round face	Shoot three-quarter view, light side of face away from camera Use three-quarter or side lighting
Thin face	Shoot front, full face Use low three-quarter or side lighting
Wide forehead	Use low-camera viewpoint Tilt chin upward
Narrow forehead	Use high-camera viewpoint
Baldness	Use low-camera viewpoint Little or no hair light Blend head with background
Eyes close together	Shoot three-quarter pose
Eyes far apart	Shoot three-quarter pose
Small eyes	Shoot three-quarter pose Use three-quarter lighting so the eyes are in shadow
Large or protruding eyes	Use high three-quarter lighting Lower eyes slightly
Deep set eyes	Low-camera viewpoint Use frontlighting to keep eyes out of shadow
Uneven eyes	Turn head toward one side so natural perspective eliminates uneven appearance
Bags under eyes	Use makeup. Use frontlighting
Cross eyed or defective eye	Turn head so bad eye is away from camera. Light side of face toward camera to place other eye in shadow

Table 7-1.–Corrective Treatments–Continued

Problem	Treatment
Glasses	Use high front, three-quarter, or side lighting to eliminate reflections Raise the temple piece up slightly to angle lenses down lilt head downward Shoot full-face pose to prevent lenses from splitting cheek line Use indirect diffused lighting
High cheeks	Use low front or side lighting
Wide cheeks	Shoot three-quarter pose
Small ears	Turn head so camera sees only one ear Place exposed ear in shadow
Large ears	Turn head so camera sees only one ear Place exposed ear in shadow
Protruding ears	Turn head so camera sees only one ear Place exposed ear in shadow Shield light from exposed ear Blend ear into background
Long nose	Use low-camera viewpoint Use three-quarter or side lighting Apply dark makeup to tip of nose
Short nose	Use high-camera viewpoint Use frontlighting
Hooked nose	Shoot from a low-camera viewpoint Shoot front, full face
Crooked nose	Shoot from the side to which it curves Turn head until highlight along ridge of nose appears straight
Broad nose	Pose head away from a front view
Narrow mouth	Use lip color to extend lip line Turn head to one side so makeup is not apparent Position modeling light high to cast shadows at ends of lips
Wide mouth	Pose head in three-quarter view
Protruding lips	Use low-modeling light to eliminate shadow under lips
Thin lips	Fill out with lip color
Uneven mouth	Pose head in three-quarter view
Bad teeth	Do not have subject smile
Buck teeth	Subject may smile slightly Use full, front pose
Long chin	Use high-camera viewpoint

Table 7-1.–Corrective Treatments–Continued

Problem	Treatment
Double chin	Keep chin in shadow Have subject lean forward and look at camera
Small chin	Use full, front pose Use low-camera viewpoint
Square face	Use high-camera viewpoint
Oval face with a weak chin	Use low-camera viewpoint
Short neck	Use low-camera viewpoint
Long neck	Use high-camera viewpoint Keep neck in shadow
Facial blemishes	Keep in shadow Turn bad side of face from camera Apply makeup to a pimple or sore spot

When the exposure is based on the illumination intensity of the main light, the indicated f/stop produces underexposed shadow areas of the negative. With black-and-white negative film, the underexposure to the shadow areas may not be enough to cause loss of shadow detail. This is because of the greater exposure latitude and film processing latitude of black-and-white film compared to color negative film. With color negative film, however, underexposure to the shadow areas may cause loss of shadow detail and a color shift in the shadow areas that is uncontrollable in printing. Remember, basing your portrait exposure on the fill light alone applies only when the lighting ratios are within about a 2:1 to 4:1 range. Beyond a 4:1 lighting ratio, you may have to calculate your exposure based on both the main and fill lights.

PASSPORT PHOTOGRAPHS

Passport photographs should only be provided to United States military personnel, their dependents, and employees of the federal government when required for executing official orders. Providing such photography for purposes and to individuals other than this is an infringement of the rights and commercial enterprise and may violate U.S. Navy Regulations.

Passport photographs are normally taken on Polaroid film with a camera designed for passport photographs. The photographs must portray a good

likeness of, and satisfactorily identify the applicant. Passport photographs must meet the following requirements:

- Photographs must be 2x2 inches in overall size. The image size, measured from the bottom of the chin to the top of the head (including hair), shall be not less than 1 inch or more than 1 3/8 inches. A quick method to determine the correct image size is the head should fit inside the frame of a 35mm slide mount.
- Passport photographs may be in color or black and white. Black-and-white photographs that have been tinted or otherwise colored are not acceptable. Prints which have been retouched to the extent that the applicant's appearance has been changed are also not acceptable. However, prints that have been retouched merely to eliminate shadows and lines are acceptable.
- Photographs that depict the applicant as relaxed and smiling are encouraged. Photographs should be portrait-type prints, meeting the size and image specifications listed above. Photographs must be clear, front view, full face, with a light, plain background.
- A passport photograph serves to identify the passport applicant. When glasses, a hearing aid, a wig, or similar articles are normally worn, these

articles should be worn when the photograph is made. Dark glasses with tinted lenses are not acceptable, unless required for medical reasons.

- Photographs should be made in normal street attire without a hat or other headgear that obscures the hair or hairline. Only applicants in the active service of the armed forces and who are proceeding abroad in the discharge of their official duties may submit photographs in the uniform of the U.S. Armed Forces. Other uniforms should not be worn in passport photographs.
- Photographs should be able to withstand temperatures up to 225°F (107°C) for 30 seconds.
- Photographs must be printed on thin paper so the seal and legend can be applied to the photograph.
- Automatic and self-developing prints are acceptable for passport photographs, providing they meet all other photographic specification. SX-70 and black-and-white Polaroid prints are not acceptable.

- Matte- or dull-finished photographs are preferred, but shiny or glossy prints may be accepted, provided the signature ink will stick to the surface of the photograph. Matte or other sprays designed to produce a dull or nonglossy finish should not be used.

PERSONNEL IDENTIFICATION PHOTOGRAPHY

The requirement for speed in identification photography makes it impractical to produce the same quality expected in portrait work. However, with a little attention to the details of lighting, posing, and exposure, high-quality photographs can be provided.

Occasionally, a profile or three-quarter view may be required for naturalization photographs. However, most identification photos are made with the subject facing the camera and looking straight into the lens. Since identification photographs must reveal as much facial detail as possible, very few are flattering pictures.

CHAPTER 8

COPYING

The term *copying*, as used in photography, means producing a photograph from a photograph, map, painting, or similar flat document. A document that is copied is called the “copy original” or “original,” and the products of the copying process are called “reproductions*” or “copies.” Originals are broadly classed as reflection originals and transparent originals. The photographic reproduction can be any size in relation to the original document.

Copying is a large and important part of naval photography. It provides an important service to most every aspect of the Navy—from the Intelligence Specialist giving a training lecture, to the admiral who needs 100 copies of a map for planning an invasion.

Photographic copying is an accurate, inexpensive, and quick way of reproducing originals. Copying is skilled work and you must give it the same careful attention that you give to other types of photography. Making good photographic copies is an accomplishment any photographer can be proud of. A knowledge of copying techniques extends your skill as a Navy photographer and makes you more useful to yourself and the Navy.

The process of copying is complicated by the extensive variation in the type of originals to be copied and the varying conditions under which the work is done. The materials to be copied range from simple line drawings to transparencies that are used daily aboard ship and at shore stations. Films used for copy photography are processed much the same as films for other photography. They can be processed by hand, in trays and tanks, or processed by machine.

COPY TERMINOLOGY

Copying—Photographing flat documents, such as photographs, drawings, blueprints, charts, and so forth.

Original—Material from which copies are made, such as handwritten copy, typed copy, printed matter, tracings, drawings, and photographs.

Halftone—Reproduction by printing processes, such as lithography of a photograph in which the gradation of tone is reproduced by a pattern of dots and intermittent white spaces, caused by interposing a halftone screen between the lens and the film. (See fig. 8-1.)

Figure 8-1.—Comparison of continuous tone, line, and halftone.

Line Original—A document or drawing consisting essentially of two tones (such as black and white, black and tinted, or brown and buff) without intermediate tones.

Continuous-Tone Original—Materials in which the detail and tone values of the subject are reproduced by an infinite gradation of gray densities between white and black

Copy Negative—A photographic film negative made as an intermediate from which prints are made.

Reproduction—The duplication of original copy by any photographic process.

Copyboard—The board, easel, frame, or other device for holding originals to be copied.

Reflex Copying—A method of contact printing in which light passes through the sensitized paper and emulsion, strikes the material being copied, and reflects back to the emulsion, producing a reversed reproduction of the original.

Restoration—Copying old, faded, or damaged material to produce a more presentable or legible copy.

Duplicating—Producing copies of negatives or slides for use instead of the originals.

Intermediate Positive—A positive transparency of a negative used for making more negatives.

Intermediate Negative (Interneg)—A negative made from a positive transparency that is then used to make reflection prints.

COPYRIGHT

On January 1, 1978, a new copyright statute came into effect in the United States. Some highlights from the law are given here. For specific details about the law or to gain copies of the statute and regulations, send a specific written request to the following: Copyright Office, Library of Congress, Washington, DC 20559.

Copyright Protection

Copyright is a form of protection provided by the laws of the United States to the authors of “original works of authorship” including photographs. This protection is available to both published and unpublished works. The Copyright Act generally gives the owner of the copyright the exclusive right to do and to authorize others to do the following:

- To reproduce the copyrighted work

- To prepare *derivative works* based upon the copyrighted work
- To distribute copies of the copyrighted work to the public by sale or other transfer of ownership or by rental, lease, or lending
- To display the copyrighted work publicly in the case of literary, musical, dramatic, and choreographic, or sculptural works, including the individual images of a motion picture or other photographic work

It is illegal for *anyone* to violate the rights provided to an owner of a copyright. These rights, however, are not unlimited in scope. The Copyright Act establishes limitations on these rights. In some cases, these limitations are specified exemptions from copyright liability. Generally however, it is unlawful to reproduce, without written consent of the copyright owner, any material bearing a notice of copyright. The guiding rule in copying is to secure written permission from the copyright owner before starting work

What Is Protected

Copyright protection exists for original works of authorship when they become fixed in a tangible form of expression. The fixation does not need to be directly perceptible, so long as it may be communicated with the aid of a machine or device. Copyrightable works include the following categories:

- Literary works
- Musical works, including any accompanying words
- Dramatic works, including any accompanying music
- Pantomimes and choreographic works
- Pictorial, graphic, and sculptural works
- Motion pictures and other imaging works and sound recordings

This list is illustrative and is not inclusive of the categories of copyrightable works. These categories should be viewed quite broadly.

What Is Not Protected

Several categories of material are generally not eligible for statutory copyright protection. Among others include the following:

- Works that have not been fixed in a tangible form of expression
- Titles, names, short phrases, and slogans; familiar symbols or designs; mere variations of typographic ornamentation, lettering, or coloring; mere listings of ingredients or contents
- Ideas, procedures, methods, systems, processes, concepts, principles, discoveries, or devices, as distinguished from a description, explanation, or illustration
- Works consisting *entirely* of information that is common property and containing no original authorship; for example: standard calendars, height and weight charts, tape measures and rules, and lists or tables taken from public documents or other common sources

Copyright Secured Automatically upon Creation

The way that copyright protection is secured is frequently misunderstood. No publication or registration or other action in the Copyright Office is required to secure a copyright under the law. Copyright is secured *automatically* when the work is created, and a work is “created” when it is fixed in a copy or imaging recording for the first time. In general, “copies” are material objects from which a work can be read or visually perceived either directly or with the aid of a machine or device, such as books, manuscripts, sheet music, film, videotape, or microfilm. Phonograph records are material objects embodying fixations of sounds (excluding, by statutory definition, motion picture sound tracks), such as audio tapes and phonograph disks. Thus, for example, a song (the “work”) can be fixed in sheet music (copies) or in audio recordings, or both.

Notice of Copyright

When a work is published under the authority of the copyright owner, a notice of copyright should be placed on all publicly distributed copies. This notice is required even on works published outside of the United States. Omission or errors will not necessarily result in forfeiture of the copyright. Therefore, just because a copyrightable material does not have a copyright notice does not mean it is not copyrighted. However, infringers misled by the omission or error of copyright notice will be shielded from liability.

How Long Copyright Protection Lasts

The copyright law changed in 1978. The time that the copyright on original material expires is determined by when it was created.

WORKS ORIGINALLY COPYRIGHTED ON OR AFTER JANUARY 1, 1978.—A work that is created (fixed in tangible form for the first time) on or after January 1, 1978, is automatically protected from the moment of its creation. It is ordinarily given a term enduring for the author’s life, plus an additional 50 years after the author’s death. In the case of a joint work prepared by two or more authors that did not work for hire, the term lasts for 50 years after the last surviving author’s death. For works made for hire and for anonymous and pseudonymous (fictitious name) works (unless the author’s identity is revealed in Copyright Office records), the duration of copyright is 75 years from publication or 100 years from creation, whichever is shorter.

Works that were created before the 1978 law came into effect, but were neither published nor registered for copyright before January 1, 1978, have been automatically brought under the statute and are now provided federal copyright protection. The duration of copyright for these works is generally computed in the same way as for new works: the life plus 50 and the 75 or 100 year terms apply to them as well. However, all works in this category are guaranteed at least 25 years of statutory protection.

WORKS COPYRIGHTED BEFORE JANUARY 1, 1978.—Under the law in effect before 1978, copyright was secured either on the date a work was published or on the date of registration if the work was registered in unpublished form. In either case, the copyright endured for a first term of 28 years from the date it was secured. During the last (28th) year of the first term, the copyright was eligible for renewal. The new copyright law has extended the renewal term from 28 to 47 years for copyrights that were still in existence on January 1, 1978.

International Copyright Protection

There is no such thing as an “international copyright” that will automatically protect an author’s writings throughout the entire world. Protection against unauthorized use in a particular country depends, basically, on the national laws of that country. However, most countries do offer protection to foreign works under certain conditions, and these conditions have been greatly simplified by international copyright treaties and conventions.

The United States is a member of the Universal Copyright Convention (UCC). Generally, a work by a national or resident of a country that is a member of the UCC, or a work first published in a UCC country, may claim protection under the UCC.

Works of the United States Government

Works produced for the U. S. Government by its officers and employees as part of their official duties are not subject to U.S. copyright protection. The law makes it clear that this prohibition applies to unpublished works as well as published ones.

Fair Use

U.S. copyright laws specifically recognizes the principle of “fair use” as a limitation on the exclusive rights of copyright owners. The law considers factors in determining whether particular uses fall within this category. Listed below are the minimum standards of educational fair use of copyrighted works under the law. The guidelines are not intended to limit the types of copying permitted under the standards of fair use.

I. SINGLE COPYING FOR TEACHERS:

A single copy may be made of any of the following by or for a teacher at his or her individual request for his or her scholarly research or use in teaching or preparation to teach a class:

- A. A chapter from a book
- B. An article from a periodical or newspaper
- C. A short story, short essay, or short poem whether or not it is from a collective work
- D. A chart, graph, diagram, drawing, cartoon, or picture from a book, periodical, or newspaper.

II. MULTIPLE COPIES FOR CLASSROOM USE:

Multiple copies (not to exceed in any event more than one copy per pupil in a course) may be made by or for the teacher giving the course for classroom use or discussion *provided that*:

- A. The copying meets the test of brevity and spontaneity as defined below; and,
- B. Meets the cumulative effect test as defined below; and,
- C. Each copy includes a notice of copyright.

III. PROHIBITIONS AS TO I AND II ABOVE:

Notwithstanding any of the above, the following shall be prohibited:

A. Copying shall not be used to create or to replace or substitute for anthologies, compilations, or collective works. Such replacement or substitution may occur whether copies of various works or excerpts therefrom are accumulated or are reproduced and used separately.

B. There shall be no copying of or from works intended to be “consumable” in the course of study or of teaching. These include workbooks, exercises, standardized tests, and test booklets and answer sheets and like consumable material.

C. Copying shall not:

- 1. substitute for the purchase of books, publisher’s reprints, or periodicals;
- 2. be directed by higher authority; and
- 3. be repeated with respect to the same item by the same teacher from term to term.

D. No charge shall be made to the student beyond the actual cost of the photocopying.

Each Navy photo lab should have a copy of SECNAVINST 5870.5, *Permission to use Copyrighted Materials in the Department of the Navy*. All Photographer’s Mates should be familiar with its general content. It should be the basic instruction you should use when the question of copyright comes up. Here are a few excerpts from the instruction:

“As a general proposition, copyrighted works may not be used without permission of the copyright owner. Unauthorized use is a copyright infringement, . . . the U.S. Government has no general exemption from copyright infringement liability. Government employees are not, however, personally liable for copyright infringement occurring in the performance of their official duties.”

“ . . . it is a criminal offense to remove or alter any notice of copyright appearing on a . . . copyrighted work, . . . ”

COPY RESTRICTIONS

Federal laws regulating photography are intended to prevent counterfeiting and fraud and are located generally in Title 18 of the United States Code.

Designated government officials are charged with safeguarding the nation’s currency. It is the belief of the United States Secret Service that granting permission to photograph and reproduce pictures of money, in color,

DEFINITIONS:

Brevity :

1. Poetry: (a) A complete poem if less than 250 words and if printed on not more than two pages, or (b) from a longer poem, and an excerpt of not more than 250 words.

2. Prose: (a) Either a complete article, story, essay of less than 2,500 words, or (b) an excerpt from any prose work of not more than 1,000 words or 10% of the work, whichever is less, but in any event a minimum of 500 words.

Each of the numerical limits stated in 1 and 2 above may be expanded to permit the completion of an unfinished line of a poem or of an unfinished prose paragraph.

3. Illustration: One chart, graph, diagram, drawing, cartoon or picture per book or per periodical issue.

4. "Special" works: Certain works in poetry, prose, or in "poetic prose" that often combine language with illustrations and which are intended sometimes for children and at other times for a more general audience that fall short of 2,500 words in their entirety. Paragraph 2 above notwithstanding such special works may not be reproduced in their entirety; however, an excerpt comprising not more than two of the published pages of such special work and containing not more than 10% of the words found in the text thereof, may be reproduced.

Spontaneity:

1. The copying of the material is for only one course in the school in which the copies are made.

2. Not more than one short poem, article, story, essay or two excerpts may be copied from the same author, nor more than three from the same collective work or periodical volume during one class term.

3. There shall not be more than nine instances of such multiple copying for one course during one class term.

The limitations stated in 2 and 3 above shall not apply to current news periodicals and newspapers and current news sections of other periodicals.

seriously weakens the safeguards designed to protect our currency.

As a Navy Photographer's Mate, you may be asked to copy United States and foreign financial certificates, such as obligations and securities. These may be needed for anything from the station newspaper to criminal investigations.

Provided below is information and conditions under which you are permitted to make copies of United States and foreign obligations and securities.

Paper Money, Checks, and Bonds

Printed illustrations of paper money, checks, bonds, and other obligations and securities of the United States and foreign governments are allowed for educational, historical, and newsworthy purposes. Illustrations must be in black and white and must be less than 3/4 or more than 1 1/2 times the size of the genuine original. No individual facsimiles of such obligations are permitted, and no illustrations of paper money, checks, or bonds may be in color.

To be permissible, an illustration must be accompanied by educational, historical, or newsworthy information relating directly to the item that is illustrated. Illustrations used primarily for decorative or eye-catching purposes are not allowed.

Motion-picture film and slides of paper money, checks, bonds and other obligations and securities of the United States and foreign governments are permitted in black and white or in color for projection upon a screen or for use in telecasting. Treasury regulations permit the illustration of United States bonds in connection with a campaign for the sale of such bonds.

United States and Foreign Postage Stamps

Printed illustrations of canceled and uncanceled United States postage stamps are permissible for articles, books, journals, newspapers, educational, historical, and newsworthy purposes.

Black-and-white illustrations may be of any size. Colored illustrations of canceled United States postage stamps may be of any size. However, illustrations in color of uncanceled United States postage stamps must be less than 3/4 or more than 1 1/2 times the size of the genuine stamp.

Printed illustrations of canceled foreign stamps in black and white or color are permissible in any size and for any purpose.

Black-and-white and color illustrations of uncanceled foreign postage stamps are permitted for educational, historical and newsworthy purposes,

Black-and-white illustrations may be of any size, but color illustrations must be less than 3/4 or more than 1 1/2 times the size of the genuine stamp.

Motion picture films and slides of the United States and foreign postage stamps are permissible in black and white or in color for projection upon a screen or for use in telecasting.

Revenue Stamps

Regulations for printed illustrations of United States and foreign revenue stamps are the same as for postage stamps, except colored illustrations of United States revenue stamps are not permitted.

Coins

Photographs or printed illustrations, motion-picture film or slides of the United States and foreign coins may be used for any purpose.

With few exceptions, existing law generally prohibits the manufacture, sale or use of any token, disk, or device in the likeness or similitude of any coins of the United States or of any foreign country that are issued as money.

Title 18, U.S. Code, Section 481

Whoever, except by lawful authority as described in the foregoing, prints photographs, or makes, executes, or sells any engraving, photograph, print, or impression in the likeness of any genuine note, bond, obligation, or other security, or any part thereof, of any foreign government, bank, or corporation, shall be fined not more than \$5,000 or imprisoned not more than 5 years, or both.

Destruction of Prints and Negatives

The negatives and prints of any United States obligation or foreign obligations produced for any of the purposes mentioned previously in this chapter must be destroyed after their final use.

COPY EQUIPMENT

The amount and type of copy work performed in an imaging facility should be the basis for the types of copy equipment on hand. When expensive equipment is not justified or available, a 35mm camera and the sun can be used for copying; however, the best results are obtained when cameras and equipment designed for copying are used.

Copying with a 35mm Camera

When making slides or only when an occasional copy job is requested, a 35mm camera should be used. Copy stands are available for use with 35mm cameras. (fig. 8-2) A set of lights may be mounted on the stand. When lights

302.180X

Figure 8-2.—Copy Stand.

are not provided with the copy stand, regular studio lights can be used in their place.

When a copy stand is not available for use with a 35mm camera, the camera can be used on a tripod, mounted for either horizontal or vertical copying. For vertical copying, the tripod elevator post is removed and inserted into the tripod upside down. The camera is then mounted under the tripod, and the tripod is then centered over the original to be copied.

Cameras for Copying Large Originals

When the copy work done in your lab is considerable and includes many large originals, the type of copy setup used by the graphic arts shops may be needed.

The type of camera used in graphic arts photography is called a process camera. Although larger than other types of cameras, it is similar in principle. Since the

process camera is built for copying, it has a copyboard and other features not associated with the average camera. There are two types of process cameras: horizontal and vertical.

Most horizontal process cameras are known as darkroom cameras because the camera back is built into the darkroom wall. Because the back of the camera extends into the darkroom and the front is housed in a separate room, you can load the film, focus the camera, make the exposure, and develop the film without leaving the darkroom. Of course, it is necessary for you or a helper to go outside to place copy in the copyboard before the exposure is made.

In recent years, vertical process cameras have become more popular because they take up much less floor space. This makes them especially useful aboard ship.

CAMERA ADJUSTMENTS.—Each copy camera has slightly different adjustments. You should consult the operating manual of your copy system to learn the proper operation and controls of your particular system. Only the minimum basic components of a copy system are discussed in this chapter.

GROUND GLASS FOCUSING.—Ground glass focusing is essential for exacting copy work. The image of a document viewed on the ground glass of a copy camera provides a means of monitoring all aspects of the image as it will appear in the reproduction. This includes image placement, image size, and any apparent unwanted reflections.

BELLOWS EXTENSION.—A copy camera should be capable of a bellows extension of at least two, and preferably three times or more the focal length of the lens being used. With a 3-inch lens and a bellows extension of two focal lengths (6 inches) and the original is positioned four focal lengths (12 inches) from the film plane, a 1:1 ratio of the original size to reproduction size is obtained. A reproduction with a 1:1 ratio can be referred to as “life size.” A bellows extension that is less than two focal lengths cannot produce an image as large or larger than the original. A bellows that can be extended more than two focal lengths can produce an image larger than the original.

LENSES FOR COPYING

A primary requirement for a lens used for copying is that it must focus sharply across a flat plan; that is, it must produce a sharp image over its entire field of view—all the way out to the edges of the image. In copying, the original has only two dimensions, and the loss of definition at the edges of the image is much more serious than it would be when photographing a three-dimensional subject.

Regular camera lenses of good quality can produce fair to good copy negatives. But most lenses for general photography are designed to focus at a flat field for distances greater than eight times the focal length. Since most copy work is done at close distances, the image field is not sharp because of the curvature of the general lens. This effect can be compensated for by stopping down the lens. However, because of the high degree of diffraction at small apertures, stopping down reduces the overall sharpness of the image. For critical copy work, such as when copying large, detailed originals, a lens designed for copying should be used. Such lenses, called process lenses, produce the best image at a lens-to-subject distance of about 10 feet or less.

Another very important aspect of a process lens is its evenness of illumination across the focal plane. Evenness of illumination across the entire negative is particularly important when copying line originals. The high-contrast films used to copy line originals have a short exposure latitude and any falloff in illumination results in obvious variations in exposure between the edges and the center of the negative.

For each lens there is an optimum aperture at which the lens produces the best image definition. For copy work, this optimum aperture should be used whenever possible. Since originals to be copied are flat or almost flat, an increase in depth of field by stopping down from the optimum aperture is not required or desired. With some lenses, especially process lenses, the optimum aperture and maximum aperture are the same. Generally, however, the optimum aperture is two full f/stops smaller than the maximum f/stop.

Most process lenses available today are apochromatic. They are designed to be free of chromatic aberrations; that is, they focus sharply all three primary colors in the same plane. Apochromatic lenses must be used for critical work in color copying and duplication.

Since exposure times in copy work are relatively long (i.e., seconds as compared to hundredths of a second), a lens equipped with a means of holding the shutter open is required. Your copy system must be completely free of vibration to obtain sharp images. For these long exposures, you must use the T and B settings and a cable release.

The focal length of a lens used for copying should be governed primarily by the size of the negative to be produced. For example, the focal length should be about equal to the diagonal measurement of the negative to be made. Therefore, when you are making 35mm negatives, use about a 1 3/4-inch or 45mm lens; a 4.5 x 6cm negatives, use a 3-inch or 75mm lens; and for 4 x 5 negatives, use a 6 1/4-inch or 160mm lens; and so on. In any case, you should use a lens that is longer than the film diagonal rather than a lens that is shorter. This way, you are taking advantage of the flatter field that is produced in the center area of the circle of illumination. A macro lens should be used when available because it is designed to produce sharp images at close planes.

COPYBOARD

Copyboards are an integral part of a copy system. The function of a copyboard is to hold the original flat and perfectly parallel to the lens and camera back. When the copyboard is not parallel, distortion results, and it

becomes difficult to get the entire subject in sharp focus. In some cases, the copyboard of the camera is a bed with a hinged glass cover. The original to be copied is placed on the bed and the glass cover is closed. When the cover is closed, the bed squeezes the original against the glass cover to flatten and hold it in place.

Reference lines are generally marked on the felt or rubber surface of the copyboard to aid in centering and aligning the copy. When the copyboard does not have these lines, draw your own on the copyboard or on a piece of paper and fasten it to the copyboard.

Some copyboards have a vacuum pump that provides suction to hold the copy flat to the copyboard. This eliminates the need for a glass cover. After the copy is placed on the copyboard, the pump is turned on and the vacuum holds the original in place.

When the copyboard does not have a vacuum pump or glass cover, originals can be held in place with pushpins. When it is not permissible to put holes in the edges of the original, then double-sided tape may be an alternative. When the copyboard is made of steel, the original can be held in place with bar magnets.

When a camera is not equipped with a copyboard and for occasional work, a copyboard can be made from a sheet of softwood or cork. The surface should be painted flat black, never white. A white, or even light-colored copyboard, reflects too much light into the camera lens, causing flare and troublesome reflections. Flare causes a loss in contrast and extra compression of the shadows. A black copyboard minimizes flare.

Always keep the glass of a copyboard clean. Dust it with a clean camel-hair brush and clean it with a soft cloth and glass cleaner. Never use dirty rags or razor blades to clean the glass. They may scratch it. When you have to scrape the glass, use your fingernail or an orange stick.

LIGHTING EQUIPMENT

Almost any type of light can be used for copy work, provided the intensity of the light is enough to prevent excessively long exposures. Another principle requirement of the light source is to produce a light with a color temperature suitable for the type of film being used.

Tungsten Lamps

Tungsten lamps 3200 K and 3400 K are suitable for normal black-and-white copy work. When a reflector type of bulb is used, the need for external reflectors is

eliminated. A lens shade should be used with a reflector type of bulb because the built-in reflector does not extend the full length of the bulb, and stray light may reach the lens and cause flare.

Lamps such as 3400 K are not as economical to use as 3200 K lamps because of their short life (4 to 6 hours).

Fluorescent Lights

When fluorescent tubes are used to light an original, they should be arranged to form a square—the sides of which are parallel to the edges of the copyboard. The size of the tubes and their distance from the copyboard are governed by the size of the original to be copied. Because this type of lighting setup is not easy to adjust, it is best used when the size of the originals to be copied does not vary much from one to another. Because of its diffused nature, fluorescent lighting is suitable for copying originals with a textured surface that must be eliminated in the finished print. Regular fluorescent lights should not be used when shooting color film because it is difficult to color correct them accurately. Special fluorescent lamps with a high color-rendering index (CRI) should be used whenever possible. When ordinary fluorescent lamps are used, consult the *Photo-Lab-Index* to determine what filter should be used as a starting point for the type of film you are using.

Electronic Flash

When used properly, electronic flash units are an excellent light source for copy photography. An electronic flash unit allows for extremely short exposures that can be helpful for shipboard photolabs when the ship is underway. The flash unit is balanced for daylight color film and does not produce the heat associated with tungsten or quartz bulbs.

Unless specifically designed for copy work and attached to the copyboard, electronic flash lamps may be difficult to position for proper illumination of the original. The task can be made easier if you use studio electronic flash units with built-in tungsten modeling lights. With this type of lighting unit, the modeling light can be used to position the lights accurately for even illumination of the original. Even with this, the light may have to be heavily diffused to prevent “hot spots.” A hot spot is a surface area that receives too much light, causing an unwanted reflection that is noticeable in the final copy product.

Quartz-Iodine Lamps

The quartz-iodine lamps (tungsten-halogen) are of the incandescent variety but bear little resemblance to conventional light bulbs. A quartz lamp is a short tube of quartz glass, housing a coiled filament that runs the length of the tube. In ordinary tungsten lamps, the tungsten evaporates from the filament and settles on the glass and gradually darkens the bulb. In the quartz-iodine lamp, however, iodine vapor combines chemically with the tungsten and causes it to redeposit on the filament. This prevents the tube from becoming tarnished with age. The intensity and color temperature of the tube remain almost constant throughout its life. Although the quartz-iodine lamp is very small, it produces intense light that is particularly suited for copy work. There is a disadvantage-quartz-iodine lamps generate extreme heat that could cause your original to curl. You should never touch a quartz-iodine lamp with your fingers. The oil from your hands can create a concentrated hot spot on the lamp, causing it to bubble and burn out.

LAMP REPLACEMENT.—As lamps get older, their color characteristics and light intensity may change. Therefore, when one lamp in a set burns out, the new replacement lamp is usually brighter and has a different color temperature than the remaining lamps. You should replace all the lamps, not just one to avoid the need for adjusting the new lamp to get even illumination. Replacement of all lamps in a set is particularly important when you are copying with color film because the color temperature of the new lamps is higher than the old lamps. The variation in color temperature would be seen as an uneven color quality over the resulting reproduction.

VOLTAGE VARIATIONS.—Fluctuations in the voltage or electric current affect the color temperature of copy lights. When the voltage to your copy lights varies, consult an electrician. The electrician can trace the source of fluctuation and recommend the best action to overcome the problem.

Parabolic Reflectors

An important element of the lighting equipment for copy work is the reflectors. Parabolic reflectors should cause the light to be evenly distributed over the surface area of the original and not cause hot spots. Certain types of lights, such as reflector photoflood lamps, have built-in reflectors. By use of the correct reflectors with artificial light sources, exposure times can be shortened.

Daylight

Daylight can be another excellent source of illumination for copying. When the sun is used, you should try to use the sun during the midday hours where a combination of daylight and skylight is present, because of the shifting of color temperature throughout the day. The early morning and evening hours should be avoided when color film is used, because the lack of blue light present. Heavy overcast skies or copying in shadow produces a bluish cast and should be avoided or corrected with a filter.

Filters

The use of filters was fully discussed in chapter 3. Both correction and contrast filters, as well as special filters, are used extensively in copy work

FILMS FOR COPYING

For copying, you can achieve the best results by selecting the correct film for the type of copy work to be done. Copy-type films are designed specifically to compensate for the compression that occurs in tone reproduction and it provides an improved highlight tonal separation. Copy films are available only in 70mm and sheet film formats. Although 35mm film can provide acceptable results, you should use sheet film since it provides higher-quality enlargements and is easier to retouch.

Film characteristics, such as color sensitivity and contrast, are important when you select the film to copy a specific type of original. Film characteristics were discussed in chapter 2.

SELECTING THE PROPER FILM

The following factors should be considered when choosing the proper film:

- ◆ The color of the original to be copied
- The contrast of the original
- The contrast of the film
- ◆ The type of product to be produced, that is, black-and-white or color print, duplicate negative, color or black-and-white transparency, and so on
- Color quality of the light source
- Types of film available

- Color sensitivity of the film
- Filters available

Black-and-White Line Originals

A black-and-white line original has no middle or intermediate tones between the lines and background. Therefore, the best film for copying black-and-white line originals is one with extreme contrast, such as Kodak Kodalith film. These films produce high contrast and extremely high density with an absence of fog, which ensures clear lines on a dense background.

Kodalith type of films have a very limited exposure latitude, and therefore, must be given very accurate exposure. Underexposure produces low-contrast negatives that result in prints having a muddy gray background instead of a clear, crisp, white background. Overexposure causes weak or very fine lines to fill in and results in a less than perfect transparency of the lines on the negative.

Typewritten material should be included in this type of original. When an original is typed or printed on thin white paper and on one side only, you should place another sheet of white paper behind the original to copy it. This increases the reflective ability of the original and increases contrast. When the original is printed or typed on both sides of thin white paper, place black paper behind the original to help prevent the printing or type on the reverse side of the original from showing through.

Colored Line Originals

In copying colored line originals to a black-and-white reproduction, you must maintain the high contrast between the lines and the background. This is best achieved by using a high-contrast panchromatic film, such as Kodak Contrast Process Pan film and a filter. When the lines or subject is to be rendered light against a dark background, the filter should transmit the color of the subject and absorb the color of the background. When the subject is to be rendered dark against a light background, the filter should absorb the color of the subject and pass the color of the background.

For example, a blueprint has white lines on a blue background. Copying the blueprint with Kodalith Pan film without a filter cannot produce maximum contrast because the film is highly sensitive to blue light and thus records the image of the blue background as a midtone of gray while recording the white line image as a dense highlight. When a red filter is used, the white lines still record as a dense highlight on the negative, but now the

blue background records as a shadow area because the red filter absorbs the blue light reflected from the blue background. Thus the background reproduces darker when a red filter is used.

Black-and-White Continuous-Tone Originals

To reproduce the tone gradation of a continuous-tone original, you must use a long-scale film. As discussed previously, a commercial type of film, such as Kodak Commercial film, is recommended.

The common fault in continuous-tone original copying is underexposure and overdevelopment. Full exposure with restrained development is the best rule for this type of work

Although appearing as line originals, handwritten material, pencil drawings, and so forth, are actually continuous-tone originals because of the midtones they contain. These should be copied as continuous-tone originals. Films, such as Kodak Professional Copy film or Kodak Commercial film, are recommended.

Colored Originals

When a black-and-white reproduction of multicolored reflection originals, such as color photographs, oil paintings, and so forth, is to be made, it should be copied with a moderate contrast, panchromatic film capable of recording numerous shades of gray. Panchromatic, long-scale film is recommended for copying this type of color original.

Colored originals are almost limitless in their degree of difference because of all the possible colors and hues. Each different colored original should be copied on the basis of what is desired in the black-and-white reproduction.

Color Reproduction of Color Originals

Selecting a film for copying colored reflection originals to make color reproductions is a matter of what type of reproduction is needed—reflection or transparency. Films, such as Kodak Vericolor III Professional Film Type L and Type S and Vericolor Internegative Film, can be used to produce color reflection copies. Color transparency film must be used to produce color transparencies from reflection originals. Some films have a different recommended ISO rating when used with tungsten or daylight light sources. Be sure to consult the data sheet supplied with the film or the *Photo-Lab Index* to determine the proper ISO setting.

When you are copying a color print to a color negative, the best film to use is Kodak Internegative film. Because of the inherent high contrast of photographic papers, if not controlled, contrast is gained in each generation of a reproduction. Kodak Internegative film is designed to give greater contrast separation in the highlights without raising the overall subject contrast in the negative. To achieve proper color balance in the shadows, midtones, and highlights, you must perform tests to assure that proper exposure and color filtration is obtained. The *Photo-Lab Index* contains the procedures necessary to accomplish this testing.

Combined Black-and-White Line and Continuous-Tone Originals

When a black-and-white original contains both line and continuous-tone matter, the ideal copy method is to copy each type of matter with an appropriate film separately and then sandwich the two negatives together, or print the two negatives separately on the same piece of paper. The colored lines should be copied with an extremely high contrast film, such as Kodalith Pan, and the pastel-colored portions of the original should be copied with a moderate contrast film.

When copying the original with only one type of film, you lose quality in either the lines or the continuous tones. For best results, you should copy the combined line and continuous-tone original with a moderate contrast film, such as Kodak Professional Copy film or Kodak Commercial film.

Black-and-White Halftone Originals

A black-and-white halftone original consists of a pattern of black dots of various sizes that represent tones of gray. Examples of halftone originals are printed pictures in newspapers or magazines. Small dots with ample white space between them produce an illusion of a light tone or highlight. Large dots that are close together produce the illusion of dark tones or shadow areas. Because the dots are all the same tone (black), halftone originals can be copied as line originals. This type of original can also be copied as a continuous-tone original, depending on the use of the final product.

Reflection Originals Specifically Produced for Copying

When an original is to be used specifically for copying, you can take certain measures to ensure better reproduction results.

PHOTOGRAPHIC PRINTS.—Black-and-white and color prints produced for copying should have normal density, color saturation, and a glossy surface. When a non-glossy surface is used, the texture of the surface may be apparent in the copy negative and reproductions.

TYPEWRITTEN MATERIAL.—Typewritten material that is to be copied should be typed with a new typewriter ribbon. A carbon “one time” ribbon is best. To further increase contrast between the type and the paper background, you can place a sheet of carbon paper behind the typing paper. This causes the carbon to be transferred onto the back of the paper during typing.

When using a typewriter to produce copy that will be photographed for making 35mm slides, limit your typing to no more than 8 double-spaced lines with 43 elite or 36 pica characters to a line. When photographing typed copy, use a template as a guide for setting up your camera. Allow about 1/8 inch of space outside the template lines in the camera viewfinder.

Originals with Defects

Occasionally, the only record of an event is the original document that through age or use is no longer in its original condition. By use of appropriate corrective measures, certain defects in originals can be eliminated or minimized in the reproduction.

WRINKLED OR CREASED ORIGINALS.—Reflection originals that are wrinkled or creased can be flattened by placing the original on a mounting board and then in a heated dry-mounting press. Mounting in this manner is permanent and should be considered carefully before being used.

Another method you can use to flatten an old photograph is to wet the photograph with water and squeegee it onto a sheet of glass with the emulsion toward the glass. The photograph must be removed from the glass before it dries; otherwise, it may stick to the glass.

STAINED BLACK-AND-WHITE ORIGINALS.—Usually, transparent stains on black-and-white originals can be eliminated in the reproduction by using panchromatic film and a filter that is the same color as the stain. Details on eliminating images of stains with filters is discussed in chapter 3.

FADED BLACK-AND-WHITE PHOTOGRAPHS AND MANUSCRIPTS.—Normally, black-and-white photographs and other types of original documents that have faded and are yellowed should be

copied with a film, such as Kodak Commercial film. An original with a weak, faded image should be copied with a film, such as Kodak Contrast Process Ortho.

SPECIAL APPLICATIONS IN COPYING

Special applications are used in copying to detect information that cannot be seen with our eyes under normal lighting conditions. Because these are special applications, they are not performed in most Navy imaging facilities, but are still worth mentioning. These methods involve the use of infrared and ultraviolet radiation and special types of films.

Black-and-White Infrared

Copying with black-and-white infrared films and infrared radiation can help in deciphering old, charred, or altered documents. This is possible because similar appearing materials can reflect and transmit invisible infrared radiation in different amounts. For example, two ink signatures may appear identical to the eye. However, when photographed with an infrared film, the two signatures may appear totally different.

A suitable infrared filter must be used when black-and-white infrared films are exposed. This is because infrared film is sensitive to visible light as well as infrared radiation. The infrared filter absorbs the visible light so the film image is produced entirely with infrared radiation. For specific filter recommendations, consult the data supplied with the film or the *Photo-Lab Index*.

Infrared wavelengths are longer than visible light wavelengths and do not focus on the same plane as visible light. Therefore, a slight increase in lens-to-film distance is necessary. A separate focusing scale for infrared is indicated on the focusing scale of most lenses.

Ultraviolet Radiation

Copying with ultraviolet (UV) radiation can aid in detecting chemically erased or badly faded writing and restoration or alteration of artwork because different materials reflect or fluoresce different amounts of ultraviolet radiation.

Photographing with reflected ultraviolet radiation in total darkness is possible because some of the ultraviolet absorbed by a material may be overlooked as visible light or fluorescence. Such photography in darkness is possible only when a material is illuminated with an ultraviolet source, such as the General Electric Uviarc. The fluorescence from a material illuminated

with ultraviolet radiation should be photographed with a No. 2A (pale yellow) filter to absorb the stronger UV reflections. A recommended film to use for ultraviolet photography is Kodak Contrast Process Ortho film. Exposure tests should be conducted to determine the best exposure for an ultraviolet copy setup.

Do not use commercial ultraviolet lamps in which the lamp itself is an ultraviolet filter. These lamps transmit visible light that does not permit photographing a fluorescing original.

COPYING REFLECTION ORIGINALS

Reflection originals are documents or other flat objects like pictures or drawings that are viewed and photographed (copied) by reflected light.

Copying reflection originals can be done with either horizontal or vertical copy cameras or setups. The size of the copy setup can range from the space necessary to attach the original to a wall and make the copy photo with a tripod-mounted camera, to a copy setup which fills two rooms- one containing the camera back and darkroom and the other the copyboard. Regardless of the different copy setups possible for reflection originals, the copying techniques are the same with few exceptions. In general, the procedures used for copy work are placing the original on the copyboard, aligning the optical axis of the lens with the original, lighting the original, focusing the lens, calculating the exposure, and exposing the film.

PLACING THE ORIGINAL ON THE COPYBOARD

A copyboard should have a positive means of attaching and holding the original. The means of attaching the original could be spring clips, small bar magnets, thumbtacks or pushpins, a hinged glass frame, a sheet of glass, vacuum, and so forth. When thumbtacks or pushpins are used, be sure not to punch holes in the original. For high volume copy, a vacuum copyboard allows a more rapid change and positioning of originals on the copyboard.

When you are using a vertical copy camera or setup, a darkroom printing easel may be used to hold the original in place.

ALIGNING THE OPTICAL AXIS OF THE LENS WITH THE ORIGINAL

Arising, falling, and sliding front feature of a copy camera provides for the alignment of the lens and the

Figure 8-3.—Lights positioned at a 45-degree angle.

original without moving the camera or the original. When the camera is not designed with a rising, falling, and sliding front, the camera or original must be moved to align the original with the optical axis of the lens.

LIGHTING THE ORIGINAL

One of the most important elements in copying is proper, even illumination of the original. Originals that are not properly and evenly lighted yield negatives with uneven density, which are hard to print. This is true whether the original is illuminated by daylight or artificial light. Uneven illumination can be caused by improper placement of artificial lights in relation to the copyboard or by improper placement of the original in daylight.

Artificial lights are normally placed on two sides of the copyboard. A 45-degree angle is recommended for general use (fig. 8-3). At this angle, a minimum of unwanted reflections from the surface of the original occurs. However, depending on the type of surface of the original, the best angle for the lights may change.

For example, an original artwork may have brush strokes that produce reflections. These reflections may be reduced somewhat by placing the lights at an angle greater or lesser than 45-degrees.

Do not position artificial lights too close to the copyboard. The circles of illumination will not cover the original completely. Movable lights should not be positioned so far from the copyboard that the intensity of the illumination falling on the original is greatly reduced.

The evenness of illumination on an original can be checked with an exposure meter. Do this by placing a gray card on the original and taking a reflected light meter reading from the card. Do not allow the shadow of the meter or your hand to influence the reading. When a gray card is not available, a white card (the back of a sheet of photo paper) can be used, but you must compensate your exposure by two f/stops. Reflected light from the four corners and center area of the original should read the same light values.

Daylight provides two choices of illumination: direct sunlight and diffused daylight, such as a cloudy, bright day or open shade. Evenness of daylight illumination is controlled by ensuring that the original is completely in direct sunlight or in diffused daylight, and no shadows are cast on the original.

Although an original is uniformly illuminated over its entire surface, apparent unevenness in illumination may still appear in the copy if a wide-angle lens is used. This is caused when the light transmitted through the center of the lens is more intense than the light transmitted near the edges of the lens. When the entire angle of view of the wide-angle lens must be used, more illumination to the edges of the original is needed to compensate for the falloff of light at the edges of the lens. This can be achieved by turning the lights slightly toward the edges or by moving the lights close to the edges. The amount of light increase necessary for the edges of the original is best determined by conducting exposure tests with the type of film being used.

Lighting control is more critical when using an extremely high contrast film, compared to a high, moderate, normal, or low contrast film. Uneven lighting is more visible in a copy produced with an extremely high contrast film because of the limited exposure latitude of the emulsion.

Figure 8-4.—Lighting large originals.

Kelvin Temperature of Illumination

When you are producing color copies, the Kelvin temperature (color) of the light source should match the color balance of the color film being used. When a light source produces an illumination color other than that for which a color film is balanced, filters must be used to alter the Kelvin temperature of the illumination to correspond with the color balance of the film.

Rises and drops in voltage also affect the color temperature and intensity of illumination. Fluctuation in voltage can be controlled by using a voltage regulator.

Lighting Large Originals

For most copy work, you should position the lights at a 45-degree angle, about 36 inches from the copyboard, and aimed at the center of the original. However, there are occasions when you may have to copy a large chart, and the normal lighting setup causes uneven illumination. Light from an artificial source must travel farther to reach the center of the original, and the light reflected from the edges must travel farther to reach the lens. This causes the light to be less intense along the edges and may result in underexposure of these areas. You can correct this condition by adjusting the lights. Keep the lights at a 45-degree angle, but move them closer to the lens optical axis until the light beams from the lamps intersect in front of the original (fig. 8-4). Balance is generally achieved when the beams cross each other at a point approximately one third of the distance from the copyboard to the lens. Check the

lighting on the ground glass or through the viewfinder to see whether it is even from the center to the outer edges.

When lighting large copy, the use of portrait lights with umbrellas is a good source of illumination. The wide coverage and diffused light, produced from this light source, allows you to light the original easily and evenly. To check the evenness of the lighting, use a flash meter and take readings from the center, corners, and intermediate points on the original.

Reflection Control

Unwanted reflections often affect copying. Proper placement of the lights is generally sufficient to eliminate most normal reflections. The three types of unwanted reflections in copy work are as follows:

- Reflections from the light source
- Reflections over the entire surface of the original or copyboard
- Optical flare

Reflections from the light source are caused by light reflecting from the camera stand, lens board, cable release, or other shiny objects around the copy setup. The reflections usually occur when you are copying glass-covered originals, glossy photographs, or other smooth-surfaced originals. The best way to eliminate this type of reflection (when changing the position of the lights does not help) is to use a black cloth or a sheet of cardboard (painted dull black) as a shield between the lens and copyboard. You can do this by cutting a hole the size of the lens in the center of the cloth or board then placing the cloth or board over or around the lens. A lens hood also helps in reducing or eliminating this type of reflection.

Reflections over the entire surface of an original can occur with rough, scratched, crumpled prints or paintings with brush marks, canvas texture, cracks, and so forth. These reflections are caused by high spots on the surface of the original and cause small light reflections of the light source. Such small reflections cover the surface of the original with a haze of light that results in a low-contrast copy image. Reflections of this type are more difficult to avoid than reflections of the light source. As long as the lights shine directly on the rough surface, such reflections occur no matter in what position the lights are placed. There are two lighting methods by which this type of reflection can be minimized or eliminated. These methods are bounce lighting and polarized lighting.

Figure 8-5.—Using bounce light to control reflections.

BOUNCE LIGHTING.—When a white surface is low enough, you should direct the light sources upward so diffused light bounces off the surface onto the original (fig. 8-5). When the surface is too high or other than white, it may be possible to use a white reflector positioned horizontally over the upturned lights. This reflector could be a large sheet of white cardboard.

POLARIZED LIGHTING.—The most efficient method of eliminating unwanted reflections in copy work is by using polarized light. In regular photography, a polarizing filter is placed over the camera lens to subdue reflections. This works because the light from the sun is polarized as it passes through the atmosphere and is reflected by the object being photographed. Using a polarizing filter over the lens only does not greatly reduce unwanted reflections in copy work. In copying, polarizing screens must be used over the lights as well as a polarizing filter over the lens.

When polarized light is used in copying, a considerable increase in exposure is required. This exposure increase is from about 10 to 16 times the normal exposure required with the same lights without polarizing screens. The exact increase is best determined through a series of exposure tests.

Reflections caused by flare are common with dirty or poor quality lenses. When available, lenses designed for copy work should be used, and like all lenses, they should always be kept clean.

DETERMINING EXPOSURE

Like all other types of photography, in copying there are various factors that must be considered when calculating exposure. You must consider the nature of the original—its color and brightness, the intensity of the

light source, the film speed, the filter factor, and the object-to-image ratio or bellows extension

Color and Brightness

Light-shaded or light-toned originals reflect more light than dark originals. Thus, with the same lighting setup, dark originals require more exposure than light originals. The amount of exposure compensation depends on the darkness or lightness of the original. When TTL (through the lens) metering is read directly from the original, a dark original may require twice the exposure of a standard exposure, and a light original may require less than 50 percent of a standard exposure. You should always use a gray or white card to determine the exposure more accurately.

Intensity of Illumination

Intensity of illumination at the copyboard can be controlled by placing the lamps closer or farther from the copyboard, by using lamps of different light intensity output, or by reducing the intensity of illumination by diffusing the light.

The best method for measuring illumination intensity at the copyboard is with an exposure meter. An exposure meter is particularly useful when the copy lights are moved or changed from the positions used to calculate a standard exposure.

The recommended ISO film speeds or exposure indices of copy films apply directly when an incident meter is used or when a reflected meter reading is taken of an 18 percent gray card at the copyboard. When a gray card is not available, a reflected meter reading of a matte white surface with about 90 percent reflectance can be taken. The back of white photo paper provides this reflectance. When a white surface is used to calculate an exposure, the ISO or exposure index of the film should be divided by 5 and rounded off to the nearest setting on the meter. For example: when the ISO is 32, divide by 5 and use 6 or the nearest setting on the meter. You also may take the meter reading directly without changing the ISO and increase the exposure by two f/stops. Remember, exposure meters are calibrated to produce middle gray regardless of the light reflectance ability of the subject. Thus the light reflectance ability of an original should be considered in determining an exposure.

The *exposure indices*, given for high contrast materials used in line copy work, are intended for trial exposures, even when an exposure meter is used.

Exposure Compensation for Bellows Extension

As discussed in chapter 4, an exposure calculated with an exposure meter is precise only for a lens set at a distance equal to one focal length. When the distance between the optical center of the lens and the focal plane is greater than one focal length, an increase to the indicated exposure is usually required. Before an accurate increase in exposure can be applied by opening the lens diaphragm, the effectiveness of the f/stop of the indicated exposure should be determined. Remember, the marked f/stops of a lens that is set beyond one focal length are not valid because the f/stops are a ratio of the diameter of the lens aperture to one focal length. Refer to chapter 4 to determine how to compensate exposure for bellows extension.

PROCESSING COPY FILMS

Films used for copying are processed the same as any other film. They can be processed by machine or by hand, using tanks or trays. Recommendations for specific developers, developing times, and developing temperatures are given with each type of film. Some films not designed specifically for copying may yield negatives with excessive contrast. This can usually be avoided by reducing the developing time. Consult the *Photo-Lab Index* to find suitable developing times to lower or raise contrast.

CATHODE-RAY TUBES

Although taking photographic images from cathode-ray tubes (CRT) is not actually a type of copy work, it has become more commonplace to photograph their images for briefs and presentations. Televisions, computer monitors, and radarscopes all can be classified as CRT photography.

When you are shooting CRTs, like all copy photography, it is important for the optical axis of the lens to be centered and perpendicular to the monitor. The camera must be mounted on a sturdy tripod. A cable release and a macro lens are recommended.

When you are photographing radarscopes, time or shutter speed is not a factor of exposure. The number of sweeps on the scope is the factor that determines the exposure at a given f/stop. The number of rotations is not proportional to film exposure. As a general rule, the exposure doubles between one and three sweeps. To get the correct exposure, you must bracket the exposure. A good starting point for less than three sweeps with ISO 125 film is at f/5.6.

To get the sharpest and clearest image possible, you must adjust the brightness of the radarscope correctly. Do this by turning up the intensity until halos appear. Then turn it down until the halos just disappear. When the intensity of the scope is too great, the image appears out of focus. If the intensity of the scope is not great enough, there is little contrast between the video and the background.

Computer-generated graphics are a common means of producing material for use in slide briefings. When available, use a computer monitor with a flat screen rather than a curved screen. Use the same procedures for shooting computer screens that you use for radarscopes. The difference is there is no sweeping motion when shooting a computer monitor or a television. When motion is apparent, you must use a shutter speed of 1/30th of a second. When you use this shutter speed, the film records the image without obvious scan lines and stops the motion of the image.

When photographing images from a CRT, always darken the room before you make the exposures. This prevents glare on the screen and only the illumination from the screen affects the film.

SLIDE DUPLICATING

In photography, you must often make duplicate slides from an original. Duplicating is actually a form of copying. A duplicate or "dupe" can be made to almost any desired size. Contrast and density along with color adjustments can be made when duplicating color slides.

Color slides are duped to provide extra copies of the slide, correct color balance and contrast errors, or even to change or enhance colors for special applications.

CAMERAS AND ACCESSORIES FOR DUPLICATING

Except for the copyboard or easel, the features of the equipment used for duplicating transparent originals are essentially the same as that used in copying reflection originals. The exception being that the copyboard for copying transparent originals must allow light to be transmitted through the original to the camera.

Except for being lit by transmitted light, large format transparent originals (larger than 35mm) are copied the same as reflection originals. 35mm transparencies are copied with special slide copying attachments for cameras, or copied in specially designed, semiautomatic or automatic slide copiers.

302.185

Figure 8-6.—Slide duplicating system.

Regardless of the equipment being used, your goals for duplicating transparent originals should be to duplicate, improve, or alter, as desired, the reproduction of the original.

DUPLICATING 35mm COLOR SLIDES

To get additional copies of a color slide, you must either make several exposures of the original scene or make duplicates from the original slide. When the scene cannot be re-photographed, the only alternative is to make duplicates of the original slide.

Other than making a number of duplicate slides from an original, you can use the duplicating process to improve a photograph. The image can be made larger or smaller, the composition can be changed through cropping, the density of the duplicates can be changed from the original, and with the use of filters, the color of the reproductions can be changed.

In most Navy imaging facilities a camera designed especially for copying slides is used (fig. 8-6). This

camera setup usually consists of a unit having a camera body and lens, bellows extension, light source, a copyboard, filter holders, and the necessary controls and switches. When slides are copied with a slide duplicating camera, the slide is transilluminated. This is the most common method of copying slides.

Exposure

Whatever method you use to copy slides, you must make exposure tests. The original slide you choose to make the tests should have average density and brightness and normal contrast. This slide should be retained as a reference slide. A full-frame slide of a color rendition chart (color checker) serves ideally as a reference slide. A color rendition chart allows you to visually or objectively compare a series of colors and densities of the original reference slide against the slide duplicate. To visually compare slides, you should use transmitted light and color viewing filters to judge the slides. The objective method is more accurate. A densitometer is used in this method. A densitometer is an electronic meter that measures the actual density of black-and-white and color materials.

Kodak Ektachrome slide duplicating film is recommended for slide duplication. This film is manufactured to provide lower contrast, less filtration with tungsten lighting, and it has good color reproduction characteristics.

The data supplied with the slide duplicating film or the *Photo-Lab-Index* provides information that you can use as a starting point for exposure tests. However, you should bracket the exposure at least one f/stop in one-half f/stop intervals on each side of the basic exposure.

Slide Handling

The original slide must be clean to produce high-quality duplicate slides. The smallest piece of dust or lint is magnified greatly when the slides are projected. Never touch a slide with your fingers. Handle the slides only by their mounts. Hold unmounted transparencies only by the edges. Dust or lint should be removed with low-pressure air or a camel-hair brush. If there are fingerprints or oily smudges on the slide, you can remove them with a soft, lint free pad or a piece of cotton dampened with film cleaner.

Slides should be placed in the slide duplicator base-side up. When you are duplicating the full frame

of the slide, you must place the slide on the copy stage horizontally, regardless of the composition of the slide. When a full frame view is not desired, you can crop or enlarge a portion of the original slide. When you change the camera or lens distance to alter the image size, be sure to refocus the image.

Examining Results

The duplicate slide should be laid on a light table and compared to the original. If you bracketed your exposure, determine which exposure provides the correct density. When none of the exposures are correct, the original must be recopied and given more or less exposure by changing the f/stop. The exposure time should not be changed. Again, bracket your exposure.

Color Balance

Color compensating (CC) filters are used in a slide duplicating camera. The CC filters are placed between the original and light source. By changing the filtration, you can correct the color balance of the duplicate slides.

After producing a duplicate slide with proper density, the color balance of the duplicate slide must be evaluated. When the color balance is off, you must change it through the use of CC filters and re-shoot the original. When the duplicate is extremely yellow, first check the slide duplicating light source. Most slide copy systems using tungsten light, have a "view setting" and a "filter setting." If the system was set in the view position, the CC filters were not in place. The unfiltered tungsten light produces a slide that is very yellow.

To judge the color balance of the duplicate slide, lay it on a light table, compare it to the original, and determine what color or colors are in excess. To do this, you should view the duplicate slides through various CC filters. A color print viewing kit is convenient for this purpose. When viewing slides through the various filters, look at the midtones, not the shadows or highlights. Color viewing filters are helpful in making color balance determinations. If a color rendition chart was used as the original slide, a densitometer can be used to directly compare the color balance of the original to the duplicate.

To adjust the filter pack for the color in excess in the duplicate slide, you should either subtract filtration of

Table 8-1.-Color Compensating Filter Factors

FILTER	FACTOR	FILTER	FACTOR
05Y	1.1	05R	1.2
10Y	1.1	10R	1.3
20Y	1.1	20R	1.5
30Y	1.1	30R	1.7
40Y	1.1	40R	1.9
50Y	1.1	50R	2.2
05M	1.2	05G	1.1
10M	1.3	10G	1.2
20M	1.5	20G	1.3
30M	1.7	30G	1.4
40M	1.9	40G	1.5
50M	2.1	50G	1.7
05C	1.1	05B	1.1
10C	1.2	10B	1.3
20C	1.3	20B	1.6
30C	1.4	30B	2.0
40C	1.5	40B	2.4
50C	1.6	50B	2.9

the color in excess or add filtration of the complimentary color to the color in excess. The amount of change required is about the same as the viewing filter required to make the midtones appear correct.

For example, when a slide is over in blue and requires a CC20 yellow viewing filter to make the midtones appear correct, a CC20 blue filter should be subtracted from the filter pack. When a CC20 blue filter cannot be removed, a CC20 yellow filter should be added to the filter pack. Your first choice should **always** be to subtract rather than add.

Adding or subtracting filters has an effect on exposure. To determine the exposure change required, you should refer to the operating instructions for the slide copier or consult a CC/CP filter factor table (table 8-1).

The number of filters used in a filter pack should be kept to a minimum. Do not combine all three filters. This only creates neutral density.

After processing, select the best exposure and use it as the basic exposure for future duplicates. When you copy other slides that are darker or lighter than the reference slide, adjust the basic exposure. Use one-half

or one f/stop more exposures for slides that are darker than the reference slide, and one-half or one f/stop less exposure for slides that are lighter than the reference slide.

You should maintain a log of the different types of copy jobs completed in your area of responsibility. With the continual changes in photographic film, processes,

and equipment, you must always perform tests (whether it be standard copy or slide duplication) to achieve the highest quality product possible. Camera distance, light source (K), light distances, film type, filters, camera settings, and processes should all be included in the log. By maintaining a log, you eliminate the necessity for photographic testing every time a routine copy job comes into your work center.

CHAPTER 9

CHEMICAL MIXING

When light-sensitive emulsions are used, photography is essentially a chemical process. You depend upon the chemical process to produce visible and permanent images. An important requirement for optimum photographic processing is the careful and correct preparation of photographic solutions. Improper mixing of chemicals or contamination during mixing can have far-reaching effects on operations, quality, production, and mission accomplishment in the imaging facilities of the Navy. It is often difficult to determine the cause of poor quality when improper chemical mixing is at fault, and the need for discarding incorrectly prepared or contaminated solutions cuts down on production and wastes money.

The main function of the darkroom portion of the photographic process is to develop film and produce prints, and this requires photographic chemistry. It may be your job to ensure that all chemicals needed are mixed and checked for quality. "This is a responsibility that you cannot take lightly." A solution that is mixed improperly may cause an entire mission to be lost. You must use the utmost precautions when mixing, checking, or analyzing the photographic solutions used in your lab.

PHOTOGRAPHIC CHEMICAL AND SOLUTION STORAGE

When you receive chemicals in your imaging facility, the cartons, packages, or containers should be dated to show either the date received or the date shipped. This helps provide proper stock rotation and systematic control of chemical usage. Chemicals should be issued from the storeroom on a first-in-first-out (FIFO) basis.

Unmixed chemicals should be stored in their original, unopened containers in a cool, dry, well-ventilated storage area where the temperature is maintained at or about 75°F with a relative humidity of about 40 percent.

Prepared solutions, like dry chemicals, also must be protected from adverse conditions, especially oxidation and contamination. When the following recommendations are adhered to, most "unused"

solutions stay in good condition for a reasonable period of time:

- Small amounts of replenisher and stock solutions are best kept in stoppered or screw-cap bottles. Glass bottles are best for developer and developer replenisher. Screw caps must be free of corrosion, foreign particles, cardboard inserts, and be airtight. Never interchange bottle tops from one bottle to another. A cap-to-bottle color or number code is suggested.

- When large bottles are used to store solutions, the air space in the bottle is increased each time the solution is removed. Since this increases the chance for oxidation, store solutions in small bottles instead. The entire contents of a small bottle can then be used at one time. However, a small air space should be left even in small bottles. This allows for varying solution volume due to temperature changes and keeps the cap from loosening or the bottle from bursting.

- When tanks are used for the storage of large volumes of solutions, they should have floating lids to protect the solutions from aerial oxidation. Dust covers also should be used to cover the top of the tank. The tank, the lid, and the cap should be coded in such a way that they are reassembled with the correct parts.

- Always follow the storage and capacity recommendations of the manufacturer. They are packaged with the chemicals. Do not use chemicals that have been in storage too long.

- Before you use any solution, no matter how long it has been mixed or in storage, check it for discoloration. Each solution has its own "signature" or characteristic appearance; and any change from normal may be a sign that it will produce unsatisfactory results. Check both sides and the bottom of the tank for precipitates. If there are any, carefully stir the solution to redissolve them. When you are unsure of the quality of the solution, discard it.

Most photo-processing chemical formulations are based on both their photographic qualities and their chemical stability or keeping qualities, both on the shelf before mixing and as prepared solutions. After long-term storage, chemicals may lose some of their chemical activity.

MIXING, TESTING, AND STORING EQUIPMENT

The type of material, used for photographic chemical mixing, solution testing, storing, as well as film-handling equipment, must be considered before mixing chemicals. Materials commonly used in the construction of this equipment are Type 316 stainless steel, polyethylene, and glass. Related equipment, such as solution transfer lines, mixer shafts, impellers, and machine parts, are also made of these same materials.

Some metals are not suitable for use with photo solutions. Serious chemical fog and developer changes can be caused by tin, copper, brass, and bronze. Aluminum, lead, nickel, zinc, galvanized iron, and Monel, when used with developers and fixers, can be harmful to films and papers. When these metals are used, silver thiosulfate from the used fixer may stick to them. Even when the utensils are washed after being in the fixer, enough silver thiosulfate can be transferred to the developer in the next processing or mixing run to cause stain, fog, or changes to image tone.

Wooden paddles and other absorbent materials must not be used with photographic solutions. Once they have been used, it is almost impossible to wash them clean of absorbed chemicals.

MIXING CONTAINERS

Chemicals should always be mixed in cylindrical containers made of suitable materials. The size of the mixing container should be suitable for the amount of solution to be prepared. A small batch of solution should not be mixed in a large vessel that uses mechanical agitation because large amounts of air may be introduced, and splashing may occur. So, the mixing container, and for that matter, scales and graduates, should be sized to the quantities and volumes of solutions required.

GRADUATES

Graduates are used to measure liquids. Graduates are made in various sizes, calibrations, and of various materials. The units of measure of graduates are calibrated in the U.S. liquid measurement system of ounces, quarts, and gallons, and in the metric liquid

measurement system of cubic centimeters, milliliters, and liters.

Glass is most commonly used for making graduates because it is NOT affected by most chemicals. Glass is also transparent and reasonably durable. Graduates are also made from plastic and stainless steel. When using graduates made of plastic, do not try to measure strong acids, such as sulfuric acid, which could cause severe damage. You must also be sure that the material the graduate is made of does not react with any of your photographic chemicals.

For accuracy in measuring liquids, graduates should be proportional in size to the quantity of solution being measured; for example, an 8-ounce graduate should be used instead of a 32-ounce graduate to measure 2 or 3 ounces.

When measuring a liquid in a glass graduate, hold it at eye level and pour the solution into it until the surface of the liquid reaches the correct mark. You will notice a curved surface on the top of the solution. This curved surface is called the "meniscus." The correct amount is indicated by the lower of two visible lines of the meniscus (fig. 9-1). These two lines can be seen easily through the side of a glass graduate when it is held correctly. With an opaque graduate, such as stainless steel, the two lines can be seen by looking down into the graduate from an angle. Stop pouring the solution when the "lower line" of the liquid reaches the calibration mark. Major divisions are indicated by numbers on the graduate. Subdivisions are shown by calibration lines only. You must determine the value of the individual subdivisions; for example, the marked or numbered lines may indicate ounces and read in series of 10. When there is only one calibration line between each graduation of 10, then the value of the calibration line is 5.

THERMOMETERS

All chemical action takes place faster at high temperatures than at low temperatures. In the photographic process, when you mix or use a solution, you must know its temperature.

Thermometers are used to measure the temperature of the solution and may be made of glass or metal. The average glass thermometer consists of a bulb, containing either mercury or colored alcohol, attached to a capillary tube. This tube may be calibrated or it may be secured to a graduated scale. When you are reading a

HYDROMETERS

Another measuring device used in photography is the hydrometer. A “hydrometer” is used to determine the specific gravity of a solution. A specific gravity check is one of the first tests to verify the dilution of a solution. When the same chemicals are used and when the same quantity of chemicals and an equal volume of water are used each time, the resulting liquid is approximately the same specific gravity each time. This is a characteristic of that particular solution when all specific gravity measurements are made at the same temperature.

The specific gravity should stay within an upper and a lower limit as determined by the manufacturer for each solution. Variations beyond the upper limit-indicating a denser or heavier liquid-suggest that more than the prescribed amount of one or more of the ingredients has been used, an ingredient foreign to the solution has been added, or not enough water was added to the solution. Measurements that fall below standard limits might indicate that something has been left out, that a foreign chemical has been substituted, or that more than the correct amount of water was added.

The silver content of a fixing bath increases as the bath becomes exhausted. This causes the specific gravity of the solution to rise. Hence, in addition to testing the consistency of chemical solutions, specific gravity tests may be used to check the amount of silver in the fixing bath. A hydrometer used for this purpose must be calibrated in grams of silver per liter of solution.

A hydrometer consists of a hollow tube with an enlarged lower section, or float, topped by a narrow stem. The lower section is weighted, so the hydrometer will float in liquids with its stem protruding from the surface. The stem is graduated with marks that are used to indicate the density of the liquid in which the hydrometer floats. When the density of the liquid is high, it supports the hydrometer more easily, so less of the stem is submerged. Less dense liquids allow the hydrometer to sink deeper.

Hydrometers are commonly graduated in terms of specific gravity. Specific gravity is the ratio of the density of a substance to the density of distilled water. However, hydrometers designed for special purposes have different types of graduated scales. An example is the hydrometer that is used to check the silver content of a fixing bath.

Because of the effects of surface tension and capillary action, a meniscus is formed at the interface between the solution and the hydrometer stem. The

237.223

Figure 9-1.—Read the lower line of the meniscus when measuring liquids

thermometer, your eyes should be level with the top of the liquid column in the capillary tube; otherwise, the reading may be off as much as 2 or 3 degrees. This error is due to the refraction of the cylindrical magnifier that is built into the capillary tube.

Most Navy photographic labs have metal, dial type of thermometers made of corrosion-resistant steel. They have a long, thin metal stem, or rod, with a circular dial indicator at the top. The action of this thermometer is remarkably fast, and the dial is easy to read.

The accuracy of all lab thermometers should be checked regularly against one of known accuracy, such as a Kodak process thermometer.

Figure 9-2.—Hydrometer.

reading is taken at the point where the top of the meniscus intersects the stem of the hydrometer (fig. 9-2).

pH METERS

The acid or alkali state of a solution is measured in pH values. The pH value of developers and fixers influences their activity and proper strength. pH is basically a measure of the degree of acidity or alkalinity of a solution. It provides an invaluable aid in determining the degree of accuracy with which the processing solutions have been prepared. Photographic developers usually have a pH of 8 to 12, while fixers range between pH 3.1 and 5.

The following scale indicates the location of acids and alkalis by their pH value (strength):

pH VALUES													
ACIDS						NEUTRAL	ALKALIS						
1	2	3	4	5	6	7	8	9	10	11	12	13	14

A pH of 7 is neutral. Working down from this point, the figures indicate weak acids with a pH of 6 on to strong acids with a pH of 1. Working up from a pH of 7, the figures indicate weak alkalis with a pH of 8 to strong alkalis with a pH of 14.

The pH values are numbered on a logarithmic scale. From 0 through 6, each number indicates a degree of acidity 1/10 as strong as the preceding number, but 10 times stronger than the next succeeding or higher number. A solution with a pH value of 4, for example, has a degree of acidity 10 times stronger than a solution with a pH value of 5, but only 1/100 the strength of a solution having a pH value of 2. When determining the degree of alkalinity of a solution, figure it in an opposite manner. From 8 through 14, each number represents a degree of alkalinity 10 times as strong as the last preceding number, but 1/10 the strength of the next higher number; for example, a solution having a pH value of 11 indicates that the solution has an alkalinity 1,000 times stronger than a solution having a pH value of 8, but it would be only 1/100 as alkaline as a solution having a pH value of 13.

Litmus paper is used to indicate whether a solution is acid, alkaline, or neutral, but it does not indicate the actual pH value. For this purpose a pH meter should be used.

A pH meter is an amplifier meter with a scale that reads from 0 to 14 and an electrode apparatus (Eg. 9-3). A pH meter has a reference electrode and a pH measuring electrode, or these two can be combined into one combination electrode. The pH electrode actually measures the pH, while the reference electrode that contains an electrolyte solution is used only to complete the electrical circuit. The first step in measuring pH is to establish a point of reference by a standardization procedure. To standardize the pH meter, you must place the electrodes in a calibrated buffer solution.

Buffer solutions are available at exact pH values for this precise standardization. Always select a buffer with a pH value as close as possible to the pH of the sample to be tested; for example, use a buffer at a pH of 4.00 to test a fixer solution or a pH of 10.00 to test a developer solution. The instrument should be standardized at regular intervals during a long series of measurements or before each use.

Courtesy of Beckman Instruments, Inc.
302.259X

Figure 9-3.—pH meter.

The ability of a pH meter to determine the pH value of a solution accurately may be used for the following purposes:

- ◆ To verify that chemicals have been properly mixed
- ◆ To test prepared chemicals
- ◆ To assure standardization of the processing solutions
- ◆ To determine the exact replenishment rates for photographic chemical solutions

Tolerances in pH values must be established for individual labs because of differences in procedures, types of equipment, impurities in water, and so forth. On the average, two readings from 10 different batches of each solution, mixed at different times, must be taken and recorded to establish these standards. These batches should be mixed as they would be for regular use but under very close control to ensure that the solutions are mixed at the correct temperature, in the proper sequence, and so forth. This operation helps in determining the tolerance. This tolerance is the amount of variation of the pH that still produces high-quality results.

Courtesy of Kreonite, Inc.

Figure 9-4.—Agitation mixers.

The discussion of pH meters is intended as an introduction only. Detailed step-by-step operating instructions for pH meters are not included in this chapter. Operating instructions in the form of technical orders and manufacturer's manuals for specific pH meters will be available to you in your imaging facility.

MIXERS

In the Navy, we use two methods of mixing chemicals: hand mixing and machine mixing. Hand mixing is used when only small quantities of solutions are needed or when machines are not available. Machine mixing is necessary to handle the large production requirements of most Navy imaging facilities.

Agitation Mixers

Proper agitation of the solution during mixing increases the rate at which the chemicals are dissolved and prevents undesirable side effects. For proper agitation, an agitator type of mixer does not cause excessive amounts of air to enter into the solution (fig. 9-4). Developers are quickly ruined by oxidation; a few minutes of improper and violent agitation can

weaken a developer and cause it to underdevelop and sometimes stain film. Too little agitation during mixing may cause the powdered chemicals to settle to the bottom of the mixer and form hard lumps. When these lumps of chemicals are undissolved and undetected, they can clog pumps and plumbing during transfer from the mixer to the storage tank. These lumps can also cause the solution to be less active.

Agitation mixers circulate solutions through a pump that causes a stirring action. There are several types of agitation mixers available. These include large capacity models for preparing large volumes of solutions and small models for making small amounts of solution.

Impeller Mixers

Impeller mixers provide thorough, rapid mixing, but they must be used with care to prevent frothing or foaming and introducing air into the solution. The solution must be mixed so a minimum amount of air is drawn into it. When the shaft is placed in the center of the container, the impeller causes a whirlpool effect that introduces excessive amounts of air into the solution. Furthermore, when the shaft is in the center of a container, there is very little agitation in the bottom-center area of the container and undissolved chemicals pile up directly beneath the end of the shaft (fig. 9-5).

Avoid bumping the shaft or impeller on the sides or bottom of the mixing vessel. This procedure may bend the mixer shaft, and a bent shaft produces excessive vibrations that can ruin the motor bearings.

WEIGHTS AND MEASURES

The different systems of weights and measures used in chemical mixing and the relationship of the various units to one another are matters that every photographer who prepares photographic solutions should understand.

These days, photographic chemicals are pre-packaged and are usually published in two systems of weights and measures: avoirdupois and metric. In the avoirdupois system, chemicals are weighed in ounces and pounds and are dissolved in pints, quarts, or gallons of water. In the metric system, they are weighed in fractions or multiples of grams and are dissolved in cubic centimeters or liters of water. With a conversion table, a formula given in one system can be easily converted to the other.

Weight and Volume Conversion

Number of Units Known	Resultant Units	Multiplication Factor
ounces	grams	28.3
pounds	kilograms	0.45
grams	ounces	0.0353
kilograms	pounds	2.2
fluid ounces	milliliters	30
pints	liters	0.47
quarts	liters	0.95
gallons	liters	3.8
milliliters	fluid ounces	0.034
liters	pints	2.1
liters	quarts	1.06
liters	gallons	0.26

Two systems of temperature measurement are used: Fahrenheit and Celsius. The Fahrenheit scale uses °F as a temperature symbol. The Celsius scale uses °C as its symbol. On the Fahrenheit scale 32 degrees is the freezing point of water, and the boiling point is 212 degrees. The difference is 180 degrees. The Celsius scale is 0 to 100 degrees from freezing to boiling. One degree Fahrenheit is smaller than one degree Celsius, one Fahrenheit degree being 5/9 of a Celsius degree. To convert Fahrenheit degrees into Celsius, subtract 32, multiply by 5 and divide by 9; that is, $(^{\circ}\text{F} - 32) \times 5/9 = ^{\circ}\text{C}$. To convert Celsius to Fahrenheit, multiply by 9, divide by 5, and add 32; that is, $(^{\circ}\text{C} \times 9/5) + 32 = ^{\circ}\text{F}$.

Some formulas use the word *parts* as a measure. They may call for two parts of one chemical, one part of another, and any number of parts of water. This is frequently done when two or more stock solutions must be combined to make the working solution. In such cases, the word *parts* means any convenient "volume" measurement may be used; however, the same measure should be used for everything required by the formula. A part may be a fluid ounce or a gallon, depending upon the total quantity of working solution needed. Formulas use parts only when volume is to be measured.

The term *stock solution* identifies a concentrated chemical solution. A working solution is the solution used for processing. The working solution may be the same as the stock solution, but more than likely it is a diluted stock solution.

Figure 9-5.—Impeller mixers.

CHEMICAL MIXING RULES

For both personal safety and efficiency when mixing processing solutions, there are a few commonsense rules that you must follow. Mixing chemicals is simple enough, but even a slight error can change the working characteristics of some solutions.

The principles of common cleanliness and precise measuring will prevent many chemical troubles. Without cleanliness and accuracy, many processes become guesswork.

Chemicals should not be mixed in areas where sensitized materials are handled or stored. Chemical

dust or fumes can ruin these materials. There should be adequate ventilation, a complete air change every 3 minutes, and an exhaust fan to the outside atmosphere in the area where chemicals are mixed.

CONTAINERS

Containers for photographic solutions should be made of a material that does not affect or is not affected by chemicals. Glass is the best material. Stainless steel is a highly suitable material, provided it is of the proper composition. Hard rubber and glazed earthenware may also be used satisfactorily. Acid and alkali-resistant plastic containers are acceptable.

Containers, graduates, sinks, and every utensil used in the photographic lab should always be clean. As soon as work is finished with an item of equipment, it should be cleaned and returned to its proper place. When chemicals are spilled, clean them up as soon as possible.

Chemical solutions and chemical dust corrode and cause pitting of most materials, including stainless steel, when allowed to remain for any length of time.

ACCURACY

Photographic quality suffers when the chemicals are improperly mixed. You must be certain that the amount of chemical you put into a solution is the amount specified.

The mixing of processing solutions has been greatly simplified over the years by the introduction of packaged photo-processing chemicals. Packaged chemicals come in convenient sizes for most needs. They offer standardized quality, economy, and convenience.

Packaged chemicals include film and paper developers and fixing solutions of various types that are manufactured under tightly controlled conditions. These packaged chemicals are available in either liquid or powder form. Processing solutions can be mixed easier, faster, and more accurately with packaged chemicals than with bulk chemicals.

When mixing packaged chemicals, you should always mix the entire package. Packaged chemicals usually contain more than one ingredient. During shipping and handling, these ingredients may separate with the heavier elements settling to the bottom of the package. When only part of the package is mixed, some of the ingredients that have separated or settled may not

be put into the solution and the result of the process is not predictable.

MIXING

Always add chemicals to the water or solution. Dry chemicals should be poured slowly into the water while it is being stirred. When preparing a developer, be careful while you are stirring so air is not beaten into the solution. When water is poured on dry chemicals, they will cake and form hard lumps that are difficult to dissolve.

Lumps or hard particles should be ground up, or crushed, with the stirring rod or with a pestle. Never add another chemical to a solution before the previous part has been completely dissolved. Sometimes there is a residue that will not dissolve. The residue may be sand in the water supply, impurities in the chemicals, or other matter that found its way into the water; however, when the solution is allowed to stand for awhile, these particles usually settle and the clear liquid can be poured off. To remove sludge or dust particles that may not settle, pour the solution through a funnel containing three or four layers of cheesecloth or absorbent cotton.

Many chemicals are very sensitive to heat, and even moderate temperatures seriously affect their chemical properties. However, the rate of chemical reaction increases with an increase in temperature, and all chemicals dissolve more readily in warm water than in cool water; consequently, many formulas and instructions recommend that water as hot as 125°F be used to prepare the solution that must then be cooled to the correct processing temperature. You should always try to mix solutions at the minimum temperature recommended by the manufacturer. Solutions oxidize faster at higher temperatures because of increased chemical activity at these temperatures.

When all crystals are dissolved, the solution should be practically colorless. Sometimes a solution appears cloudy or milky for a short time after it is mixed. This appearance may be caused by air taken into the solution by the dry chemicals. Air taken into a solution is distributed through the solution as tiny bubbles that cannot escape while the solution is being stirred. When the presence of bubbles has caused the discoloration, the solution will clear up when it is allowed to stand for a while. The bubbles rise to the surface of the solution and escape into the air.

Always add acid to the water. This is as easy to remember as AAA (Always Add Acid). It is dangerous to pour water into an acid. Some acids generate heat

rapidly enough to cause boiling or a splashing explosion that may splash the solution on someone nearby. Acids should always be poured slowly into a solution (near the edge of the container) while rapidly but carefully stirring the liquid.

LABELS

Mixing tanks, storage tanks, and machine tanks for developer, stop bath, fixer, and other solutions must be labeled clearly with waterproof tape or nameplates to reduce the chance of putting a solution into the wrong tank. The label should contain the name of the solution, the date it was mixed, and the name of the person that mixed it. It is also mandatory that hazardous chemical labels be attached to all chemical containers.

CONTAMINATION

All of the mixing equipment and the mixing area must be cleaned immediately after use to prevent solution contamination. The mixing tools and tanks must be thoroughly cleaned right after use to prevent dried solutions from forming encrustations that could dissolve when a new solution is mixed. Mixing tools that have not been used in some time should be washed before use to remove any dust or dirt that may have accumulated.

PREPARATION OF PHOTOGRAPHIC SOLUTIONS

When mixing photo chemicals, you should always start with clean tools and a clean tank with the right amount of water—usually about one half to three fourths of the final volume. The temperature of the water must be as specified in the instructions. Developers are generally mixed at or about 90°F to 125°F, while fixers are mixed in water that should not be much above 80°F.

Always dissolve or dilute ingredients in the order called for by the instructions. Dry ingredients must be completely dissolved before the next ingredient is added. All liquids must be completely diluted, while stirring, before the next ingredient is added.

After a liquid is added to a solution, rinse the bottle and add the rinse water to the solution, so all the concentrated liquid is used.

After all ingredients have been combined and thoroughly dissolved, diluted, and mixed, water should be added to bring the solution up to the correct volume. Do not forget to mix this water thoroughly into the solution.

FOLLOW DIRECTIONS

Before mixing photographic chemicals, you should read the manufacturer's directions carefully. Much research goes into the production of chemical products; however, it is only effective when the chemical is mixed and used properly. The directions for even the most familiar product should be reviewed, because there are continual attempts to improve photographic materials; for example, new film or developer combinations may call for changes in dilution, processing time, or temperature to get the required results. Learn to follow directions. This is very important in the preparation of chemicals for both quality and safety reasons.

Remember to follow the proper procedures for chemical safety. You should prepare the chemicals in a well-lighted and well-ventilated room. Do not taste or inhale any chemical. You are required to wear rubber gloves, a rubber apron, eye protection, a long sleeve shirt, and a respirator for your personal protection. Remember, for safe mixing and quality results, FOLLOW DIRECTIONS.

CAUTION

In most imaging facilities, it is common practice to connect a hose to the water spigot to aid in filling a chemical mixing tank and to prevent splashing in the sink. Aboard ship, hoses attached to potable water spigots can back siphon chemicals from the tank or sink into the drinking water supply. Such hoses should either be removed after each use or have a backflow preventor installed in the plumbing system.

CHANGING PERCENTAGES

You must know how to prepare percentage solutions from liquid chemicals. When the chemical on hand is in liquid form and of known strength, a percentage solution can easily be prepared by the following method:

$$\frac{\text{Amount Wanted} \times \text{Strength Desired}}{\text{Strength on Hand}}$$

Multiply the amount wanted by the strength desired and divide the product by the strength of the chemical on hand; for example, you need 11 ounces of 28 percent acetic acid. The chemical on hand is glacial acetic acid, 99.5 percent. Thus,

$$\frac{11 \times 28}{99.5} = \frac{308}{99.5} = 3.09 = 3 \text{ ounces}$$

Add 3 ounces of 99.5 glacial acetic acid to 8 ounces of water to obtain 11 ounces of a 28 percent solution of acetic acid.

CHEMICAL SAFETY

Some of the chemicals used in photography are skin irritants, and others can cause serious injuries. Chemicals should be regarded as poisons and handled with caution. Before handling or working with photographic chemicals, you should become familiar with the safety precautions contained in *Navy Occupational Safety and Health (NAVOSH) Program Manual for Forces Afloat*, OPNAVINST 5100.19 series, volume I (chapters B3 and B12) and volume II (chapters C1, C9, and C23), *Navy Occupational Safety and Health (NAVOSH) Program Manual*, OPNAVINST 5100.23 series (chapters 15, 20, and app. 15), and *Safety Precautions for Photographic Personnel*, NAVAIR 10-1-764.

Because of the danger of contaminating your fingers, all precautions concerning poisons should be observed when you are mixing photographic solutions.

Ingestion of a poisonous chemical is commonly induced by hands that are contaminated with a toxic chemical. You should adhere to the precautions published for photographic chemicals to avoid contact or ingestion of poisonous or corrosive chemicals. Regardless of the antidote given to anyone that has been accidentally exposed to or has swallowed a poisonous or corrosive chemical, the antidote is for EMERGENCY USE ONLY. The affected person should report to the MEDICAL DEPARTMENT IMMEDIATELY.

ACIDS AND ALKALIES

There are many types of acids and alkalies used in photography. In general, acids and alkalies are similar in their injurious properties in that either may cause the following:

- Corrosion (chemical burn) by direct contact with the skin or eyes or indirectly through the clothing.
- Intoxication or suffocation by inhalation of their fumes. The fumes of some compounds are toxic or poisonous, while others displace air, thereby producing a suffocating atmosphere.
- Poisoning when taken internally.
- Fire and explosion because of their instability under adverse storage conditions. Also, some acids are strong oxidizing agents that can generate ignition

temperatures upon contact with organic materials and other chemicals.

PRECAUTIONS

There are several safety items that must be worn when mixing chemicals. They are as follows:

1. Face shield or goggles-Protects the eyes from caustic chemicals.
2. Plastic or rubber apron-Reduces the chance of chemical contamination of clothing.
3. Rubber gloves-Protects the hands and lower arms. Gloves should extend up to the elbows.
4. Respirators-Used to prevent the inhalation of fumes or chemical dust. The correct cartridge must be used for the type of chemical being mixed as described in *Navy Occupational Safety and Health (NAVOSH) Program Manual*, OPNAVINST 5100.23 series (app. 15). Respirators must be cleaned and sanitized with alcohol and placed in an airtight bag after each use.
5. Long sleeve shirt-Used to protect the arms.

The majority of photographic chemicals cause the skin to dry out due to the removal of natural skin oils. Some types of chemistry have an accumulative nature. This is when some of the chemicals are being absorbed into the skin layers during each exposure to the chemistry. The chemistry then replaces some of the natural oils that lubricate the skin. Over an extended period of time, which varies for different people, accumulation could result in a total breakdown of the ability of the skin to produce natural fats and lubricating oils. Extreme conditions can result in contact dermatitis. Metol (developing agent) poisoning can be a result of accumulation poisoning.

Certain precautions must be observed in areas where acids and strong alkalies are handled. These precautions are as follows:

- Warning signs and labels-Signs should be posted in the chemical mixing area, warning personnel of the principal hazards of the chemical being used. All containers must be properly identified with hazardous material labels.
- Showers and eyewash stations-Showers and eyewash stations must be provided near all chemical mixing areas.

- Ventilation-In a chemical mixing area, exhaust ventilation must be provided. The exhaust vent must draw vapors away from the person mixing the chemicals and provide a complete air change once every 3 minutes (20 changes per hour).

- Mixing and diluting-Strong acids and strong oxidizing agents may react violently or produce explosive products. Toxic gases may be created when acid is mixed with such chemicals as sulfides, cyanides, nitrates, and nitrites. Diluting acids with water can generate considerable heat; acid should always be added to water, not water to acid. The addition should be done slowly with constant stirring.

- Never smell a chemical directly from the bottle; instead, hold the bottle at a distance from your nose and sniff its contents cautiously rather than inhale directly.

- Never taste a chemical.

- Handle all chemicals cautiously; many can produce burns or skin irritation.

MATERIAL SAFETY DATA SHEETS (MSDS)

In addition to the precautions listed previously, every person in your imaging facility must be completely familiar with the Material Safety Data Sheets (MSDS) for each chemical solution used in your photographic production. The MSDS are provided by all the manufacturers of hazardous materials. You are required to have the MSDS for each solution. The Occupational Safety and Health Administration (OSHA), as well as your safety officer, performs periodic safety inspections of your imaging facility. Every person is responsible for the location and information contained in the MSDS. MSDS are generally broken down into 12 sections as follows:

1. Product Information
2. Component Information
3. Precautionary Label Statements
4. Physical Data
5. Fire and Explosion Hazard
6. Reactivity Data
7. Toxicological Properties
8. Protection and Preventive Measures
9. Storage and Disposal

10. First Aid

11. Transportation

12. Preparation Information

It should be noted that separate MSDS may apply to working solutions and stock solutions or concentrates. Be certain that the MSDS apply to the chemical you are in contact with.

ENVIRONMENTAL ISSUES

The Environmental Protection Agency (EPA) has tightened regulations drastically and they have a substantial impact on the way imaging facilities conduct business. All Hazardous Materials (HAZMAT) must be handled in complete compliance with EPA regulations. The regulations and tolerances differ from state to state and base to base. It is important that you comply with the regulations in your local area.

DISPOSING OF HAZARDOUS MATERIALS

Before you pour photographic chemicals down the drain or throw material in the dumpster or over the side, you must be certain that you are not violating any hazardous material handling or disposal procedures. You should be completely familiar with the environmental protection standards and the Ship's Hazardous Material List for all items that apply to your command. EPA regulations state that anyone violating environmental protection regulations can be personally accountable and fined. When you have ANY doubt, ask your supervisor before disposing of the material(s).

The MSDS provide information on how to neutralize and clean up spill containment of photographic chemicals. When handling and cleaning up chemical spills, be sure you follow all safety precautions mentioned previously. It is important that any chemical spill be cleaned up immediately because many chemicals are extremely corrosive. These chemicals may damage or stain the surfaces with which they come into contact. Consult your local directives on disposing of materials used to clean up chemical spills as well as the chemicals themselves.

SILVER RECOVERY

Silver contained in photographic emulsions and used fixers and bleaches are considered hazardous

material. Silver recovery was established originally to reclaim the silver from these materials and reclaim for money that was returned to the Department of Defense. Today, however, when not performed, silver recovery

could be very costly in the fines that may occur when photographic materials are not disposed of properly. Be certain that you know the proper handling procedures for photographic materials that contain silver.

CHAPTER 10

IMAGE PROCESSING AND CONTROL

As a Navy photographer, you must realize that composing and exposing a scene on film does not guarantee top-quality photography. The quality of the finished print depends on the quality of your darkroom work. A perfectly exposed film is useless if it is fogged, scratched, or under- or overdeveloped. Therefore, each step of film processing is important and you must master each step.

During the discussion of *basic* film processing concepts, both black-and-white and color film processing are covered. The mechanics of black and white and color processing are very similar. The primary differences between processing color film and processing black-and-white film are there are more steps in a color film process, and the time and temperature requirements are more critical.

DEVELOPERS AND DEVELOPMENT

The purpose of development is to convert those parts of the light-sensitive material (film or paper) that has been affected by light to black metallic silver. This produces a visible image from the invisible latent image. Development is usually carried out by bringing the exposed film into contact with a solution that contains a developing agent, but no silver salt. The silver that forms the developed image comes from a reduction of the individual silver halide grains in the film emulsion. This process is called *chemical or direct development*.

In another process that is seldom used, the developed image is derived from a soluble silver salt contained in the developing solution itself. This process is called *physical development*. The physical development process can be difficult to use because there is a tendency for silver to be deposited where it is not wanted.

The process of *chemical development* is most commonly used for film development. Chemical development is the process with which you should be concerned. In chemical development, the individual silver halide grains in the film emulsion are reduced to a black metallic silver. Each grain in the emulsion acts as a unit, in the sense that a grain is either developable as a whole or is not developable. When film development is performed properly, only exposed grains

containing a latent image are reduced to black metallic silver. You may ask, "Why doesn't the developer develop the unexposed grains as well as the exposed grains?" Actually, the unexposed grains are developable. When development is carried out over a long enough period of time, all grains are developed or reduced to black metallic silver. The density that results from the development of unexposed silver halides is called *fog*. Thus development is a rate phenomenon and the development of the exposed grains takes place at a faster rate than the unexposed grains.

The individual grains of silver halide in an emulsion are protected against the action of the developer by a chemical layer. When light strikes the emulsion, it breaks down the protective layer at one or more points on each individual *light-struck* grain. When the exposed film is placed into the developer, the grains are acted upon at these points by the developing agent, and each grain that received more than minimum exposure is quickly reduced to black metallic silver. The amount of blackening (density) over the film surface depends primarily upon the number of grains that have been affected by the developer. Density is also influenced because some grains may not develop to completion in the time the developer is allowed to act on the film.

COMPOSITION OF A DEVELOPER

There are many different formulas used as developing solutions, but most developers contain the following four essential ingredients: developing agent, preservative, accelerator or activator, and restrainer.

DEVELOPING AGENT

The developing agent, commonly referred to as the *reducing agent*, is the most important chemical in a developing solution. It is the developing agent that actually converts the silver halide grains in the emulsion to metallic silver. Nevertheless, the other ingredients are necessary to make the solution function properly.

One of the properties of a developing agent is its reducing potential. This refers to its relative ability to develop or reduce the silver halides. An active developing agent attacks silver halides vigorously, whereas one of low potential is slower in its action. For

certain purposes, one agent may be preferred over another. The temperature of the solution affects the activity of some agents much more than others. Hydroquinone, Metol, paraphenylenediamine, and phenidone are some of the more commonly used developing agents.

PRESERVATIVE

All developing agents in an alkaline state are affected by oxygen. When the developing agent combines with the oxygen in the air, the efficiency of the developing agent is reduced. When elements combine with free oxygen from the air or water, *oxidation* occurs. Therefore, a preservative is added to developing solutions to prevent excessive oxidation. The preservative prolongs the useful life of the developing solution and prevents stains caused by the formation of colored oxidation products.

The preservative is a chemical with a great attraction for free oxygen and combines with it when mixed into a solution. A large amount of free oxygen is in the water used for solutions. When the free oxygen is left in the water, it oxidizes most of the developing agent and produces stains before the metallic silver image is developed completely. By adding enough preservative, you may remove practically all of the free oxygen from the solution, the developing agent works as intended, and no stains are produced. Sodium sulfite is the preservative most commonly used in developing solutions.

ACCELERATOR

All developing *agents* (not developing *solutions*) are either neutral or slightly acid. Most developing agents must be in an alkaline state to be effective reducing agents, thus solutions require an alkali to activate the developing agent. A developing *solution* contains an accelerator so the solution becomes alkaline.

The accelerator serves two functions. First, it speeds up the swelling of the gelatin in the emulsion. This swelling permits the solution to penetrate the entire emulsion more quickly. The effect of this action is physical. The second action is completely chemical. As the silver halide salts in the latent image are reduced by the developing agent, the halide elements freed from the silver are absorbed by the accelerator and combined into neutral salts. This prevents harmful effects in the solution.

Because the accelerator is a determining factor in the activity of a developing solution, it affects the degree

of graininess produced in the negative. This graininess is dependent upon the clumping action of the silver grains during the development process. The more active the developer, the higher the pH, and the greater the clumping action. Therefore, the milder or less alkaline developers yield finer grain. Common accelerators used in developing solutions are sodium carbonate and potassium carbonate.

Without an accelerator, there is little or no action. With some accelerators there is too much action. By the addition of a bromide restrainer, you may slow down the action of the developing solution to a controllable degree.

RESTRAINER

Without a restrainer most developing solutions act too rapidly and develop unexposed silver halides near the surface of the emulsion. This causes chemical fog, developing streaks, and an image with low contrast. During development, some restrainer is released from the silver and has a restraining action on the reducing agent during development. However, its action is not enough to prevent fog. When a restrainer is added, development time is prolonged and fog is minimized. Contrast is increased because the activity of the developing agent is cut down in unexposed areas. However, too much restrainer greatly retards the amount of development. The chemical most commonly used as a restrainer is potassium bromide.

TYPES OF BLACK-AND-WHITE DEVELOPERS

As stated previously, when a photographic emulsion is exposed to light, there is an invisible change produced in the minute crystals of silver halides that results in a latent image. To make the image visible, you must treat the exposed emulsion in a solution known as a developer. This solution converts the halides affected by light to black metallic silver. These black metallic silver particles form the visible image on the negative.

At the beginning of development, there is little difference in density between the highlight and shadow areas of the film. However, during normal development, this difference increases because the highlight densities continue to increase after the shadow areas are completely developed. Development should stop when the contrast between the shadows and highlights reaches a desired difference. The activity of the developer, and to some extent the type of film, primarily determines this developing action.

One type of developer cannot cover all situations; for example, film exposed by poor lighting conditions may require an active developer to bring out as much of the image as possible, while a film exposed under normal conditions requires a normal working developer. There are many different developers, each provides different activity and quality of development. The actual choice of the developer to use depends on the type of film, conditions under which it was exposed, type of negative required, and the developing time that is best for your development method.

GENERAL-PURPOSE DEVELOPERS

A developer for general-purpose work should produce moderate grain, normal contrast images. Clear areas of the negative, as well as the image areas, should be basically fog free.

Some general-purpose developers are as follows:

- HC-110
- DK-50
- Microdol

FINE-GRAIN DEVELOPERS

All photographic emulsions have a grainy structure. Although this grainy structure is not normally visible to the naked eye, it becomes visible whenever high magnifications are used to make prints. The tendency to use small-format film and make large enlargements has resulted in the need for fine-grain developers.

When enlargements are made from small negatives developed in other than fine-grain developer, the grain of the film may be objectionable. Graininess in the film should be *controlled* in the development of the film. Keep in mind, however, that every film has its own grain structure or characteristics. For 35mm-roll film, it is normally best to use a fine-grain developer.

Fine-grain developers achieve the desired result in several ways:

- They are usually soft working and this tends to reduce clumping of the silver grains.
- Some fine-grain developers actually produce smaller individual grains of black metallic silver. This, however, tends to reduce the film speed.
- The grayish white images produced by some fine-grain developers help by providing for increased

passage of light between individual grains. This results in less local variation in density.

- Most fine-grain developers produce relatively low-contrast negatives. A reduction in contrast in the negative tends to reduce the graininess of the negative. However, this may not contribute significantly to a reduction in the graininess of the final print. Any advantage achieved by lowering negative contrast may be offset by the need to use a higher contrast printing filter to print the negative.

Some fine-grain developers are as follows:

- ID-11 (Ilford)
- D-76 (Kodak)
- Atomal (Agfa)

HIGH-CONTRAST DEVELOPERS

To produce maximum contrast on process and line copy type of films, you must have a developer that produces density readily and is free from any tendency to produce fog within the time of development.

Some of the most popular high-contrast developers are as follows:

- Kodalith (Kodak)
- D-11 (Kodak)
- D-19 (Kodak)

To prevent staining when using a high-contrast developer, you should rinse the negative well between developing and fixing.

HIGH-DEFINITION DEVELOPERS

A high-definition, or compensating, developer adds increased sharpness to the image by enhancing contrast of image edges and fine detail in the negative. High-definition developers may increase film speed by one or two f/stops, but they also increase graininess. High-definition developers are recommended for use only with fine-grain (slow or medium speed) films.

Some of the high-definition developers are as follows:

- Acufine
- Ethol TEC

You should consult the film data sheets or the *Photo-Lab-Index* for the recommended developers for each particular type of film to be processed.

CHANGES IN DEVELOPER WITH USE

The function of a developer is to change chemically the sensitized material treated in it. It stands to reason then that a chemical change also takes place to the developer itself. Most developers are used more than once. Therefore, you must know what changes to the developer can be expected and what can be done to prevent them or at least compensate for them. The primary changes that occur to a developer as it is used are as follows:

- Some developer is removed or carried out with the film and on the film hangers or reels.
- The developing agents are used up by reduction of silver halides to black metallic silver and by aerial oxidation. When the developing agents are used up by the reduction of silver halides, the by-products of the reaction cause the pH of the solution to drop, thus becoming more acid. When the developer agents are used up by oxidation, the pH tends to rise.
- The preservative is used up, thus the developing agents oxidize faster.
- The bromide within the solution is increased because the bromide is released from the film emulsion itself.

The effects of these changes to a developer are as follows:

- The development time required to reach a given contrast index or gamma is increased. Therefore, when a developer is used over and over, development time must be increased as more film is developed.
- The effective film speed produced by the developer decreases because of the increased bromide (a restrainer) in solution. However, this speed loss may be partially offset by increasing development time to maintain image contrast.

Complete exhaustion of a developer occurs when the developing agents are all used up. The approach of exhaustion is characterized by a brown color of the solution. Since a developer in this state can stain sensitized materials, it should not be used.

In most Navy imaging facilities, it is not economical to use a developer to the practical exhaustion point and then discard it. The quality of the image usually suffers

long before the exhaustion point of the developer is reached. Replenishers are usually used to prevent this from happening.

Replenishment of a developer involves replacing those chemicals in the used developer that are exhausted by a replenisher so that the developer remains consistent. The aim of replenishment is not to keep the composition of the developer constant but to keep its activity constant.

There are two commonly used methods of replenishment. The first or "topping off" method is used extensively in tank processing. When topping off is used, the developer solution is maintained at a constant level in the tank by adding replenisher, so the volume added is equal to the amount of developer carried out. When you are replenishing by this method, it is possible to maintain consistency in development for only a certain period of time. After a given volume of replenisher has been added to the developer, the developer must be discarded. This procedure is then repeated with new developer.

The second replenishment method is called the "bleed" method. The bleed method is used primarily with machine processing where a circulating developer system is used. In the bleed method, used developer is drained off and replenisher (in proportion to the amount of film processed) is fed in, so the characteristics and the level of the developer in the machine remain constant.

FIXING, WASHING, AND DRYING

As soon as a light-sensitive material is developed, it contains a visible silver image, but the image is not ready to be exposed to light. Only a portion of the silver halides in the emulsion were reduced to black metallic silver by the developer. The silver halides that were not reduced restrict both the immediate usefulness and the permanence of the image. These undeveloped silver halides must be removed. This is the purpose of the fixing bath. Before treating the sensitized material in the fixer (as it is called), you must stop or at least slow down the action of the developer. When the light-sensitive material is removed from the developer solution, there is a small amount of developer both in the emulsion and on the surface that must be removed or neutralized. For this, you use either a water rinse bath or an acid stop bath.

WATER RINSE BATH

To *slow* down the action of development, you must immerse the film in a water rinse bath. A plain water rinse bath is commonly used between development and fixation to *slow down* the development by removing all the developer that is clinging to the film (or paper) surface. A rinse bath does not completely stop development but retards it. A rinse bath has little affect on the developer that is actually in the swollen emulsion.

Rinsing is accomplished by quickly immersing the film in plain, clean water. A water rinse bath should be changed often to ensure it does not become loaded with developer. It is better to use running water.

The rinse bath, then, serves two purposes: first, it slows down development and second, it reduces the work that has to be done by the acid in the fixer. Rinsing, therefore, protects or prolongs the useful life of the fixer.

Following rinsing in plain water, the material (that is still light sensitive) must be treated in an acid fixing bath to *stop* the development.

ACID STOP BATH

Although a plain water rinse bath is commonly used between development and fixation, a better procedure is to use an *acid* stop bath. The function of a stop bath is not only to remove the developer that is clinging to the surface of the material but to also neutralize the developer in the swollen emulsion to *stop* development completely.

The acid stop bath stops the action of the developer because developing agents cannot work in an acid solution. An acid stop bath also helps protect or prolong the life of the fixer by neutralizing developer carry-over.

An acid stop bath should meet the following requirements:

- The pH must be low enough to neutralize the action of the developer carried over.
- The acidity should be limited so the small amount carried over into the fixing bath does not increase the free-acid content of the fixing bath and cause sulfurization.
- It must not contain enough acid to produce blister formations in an emulsion.

You should use only a weak acid stop bath between development and fixation. Strong acid and the acid in the fixing bath have a tendency to form carbon dioxide

gas bubbles in the emulsion. When the film is taken from the developer and placed directly into a strong acid or fixing bath, these bubbles may break and cause small, round holes in the emulsion. These bubbles are sometimes mistaken for pinholes like those caused by dust particles settling on the emulsion before camera exposure.

When you are using an acid stop bath, remember that some of the stop bath is carried into the fixer when materials pass through it. Therefore, you cannot use a strong acid (such as sulfuric acid) because it can cause precipitation of sulphur in the fixer. Acetic acid is the type of acid used for stop baths. In its pure form as *glacial acetic acid* (99.5 percent), it freezes at a temperature of about 61°F. Its freezing tendency gives it the name “glacial.” For use as a stop bath, 99.5 percent glacial acetic acid is diluted with water to make a 28 percent working solution. Approximately 1/2 ounce of 28 percent acetic (not glacial) acid is added to 32 ounces of water. The process of determining the concentration of a liquid is discussed in chapter 8.

FIXING

When a light-sensitive material is removed from the developing solution, the emulsion contains a large amount of silver salts (halides) that has not been affected (developed) by the developing agents. This silver salt is still sensitive to light, and if it remains in the emulsion, light ultimately darkens and discolors the salt which obscures the image. Obviously, when this action occurs, the negative (or print) is useless.

The fixing bath is used to prevent this discoloration and to make the developed image permanent. It accomplishes this by removing the undeveloped silver halides by making them water soluble. Therefore, to make an image permanent, you must “fix” the light-sensitive material by removing all of the unaffected silver salt from the emulsion.

The fixing bath contains five basic ingredients: the fixing agent, preservative, neutralizer or acidifier, hardening agent, and an antisludge agent.

Fixing Agent

All fixing baths must contain a silver halide (salt) solvent. This solvent is known as a fixer or fixing agent. The two most commonly used in photography are sodium and ammonium thiosulfate, commonly termed *hypo* (taken from their other chemical name hyposulfite). Ammonium thiosulfate is used in rapid fixers that are stronger and require less fixing time.

Sodium and ammonium thiosulfate changes undeveloped silver halide to soluble silver sodium thiosulfate. It removes this compound from the emulsion and refills the space it occupied with nonexhausted fixing solution. Therefore, the function of the fixing agent is to convert the silver salts remaining in the emulsion after development to soluble compounds and to remove these soluble compounds by constantly diluting and replacing them in the emulsion. The number of substances capable of functioning as fixing agents is small because a good fixer must meet the following requirements:

- It must dissolve silver salts without affecting the metallic silver image.
- The compounds it forms must be soluble so they can be removed from the emulsion.
- The fixer should neither swell excessively nor soften the gelatin.

Preservative

A preservative prevents oxidation of the developing agents that are carried over into the fixing bath by the film. It also prevents decomposition of the fixer. Oxidized developer in a fixing bath produces stains.

Strong acids may cause a fixing agent to decompose (sulfurize). You must add preservative (sodium sulfite) in the fixer to prevent sulfurization. The preservative prevents the acid from decomposing hypo into free sulfur, prevents discoloration of the solution because of oxidation, and aids in preventing stains.

Neutralizer

After development, the pores of the swollen emulsion retain a portion of the developer. If allowed to remain, the developer continues its activity. Even when the emulsion is thoroughly rinsed in a water bath before being placed in the fixer, some developer activity remains. This causes uneven stains in the gelatin of the emulsion and makes the negative unusable. To stop development and prevent stains, you must add an acid neutralizer to the fixer. The most frequently used neutralizer is acetic acid.

Hardening Agent

During development, the gelatin becomes softened and swells. Frilling, reticulation, scratches, and other undesirable effects may result when processing is continued without hardening the emulsion. A hardening

agent is included in the fixer to harden the emulsion in the fixing bath. The most common hardening agent is potassium alum. The hardening and toughening of the gelatin by the alum stops the tendency of the emulsion to swell but leaves it expanded and rigid enough for the washing process.

Antisludge Agent

The pH range of the fixer is limited. It must be low enough to neutralize the activity of the developer and also be high enough to prevent sulfurization. The reduced acidity of the bath is gradually neutralized by the alkali of the developer carried into the fixer by the film. When the active acidity is neutralized too far, a sludge of aluminum sulfite forms that can make the fixer useless. An antisludge agent, such as boric acid, is added to the fixer. This agent is capable of absorbing a large quantity of the developer before sludge occurs, thus lengthening the useful life of the fixer.

Time Required for Fixing

The time required for film to fix depends on several factors:

- The type of emulsion and its thickness. All else being equal, fine-grain emulsions fix faster than coarse-grained ones. Thin emulsions require less time to fix than thick emulsions.
- The type of fixing bath and degree of exhaustion. When sodium thiosulfate is the fixing agent, a concentration of about 75 percent gives the fastest rate of fixation. However, because of the tendency of hypo to bleach out the image, most fixers for negatives have a concentration between 20 and 40 percent.
- The fixing bath temperature. An increase in the temperature increases the rate of fixation. (Do not interpret this to mean that you can raise the temperature of the fixer above the temperature called for by the particular process being used.) The temperature of the fixer is not as critical as the temperature of the developer. However, you should keep all processing solution temperatures constant to avoid an increase of graininess.
- The amount of agitation. The rate of fixation is affected by diffusion of the chemicals, so agitation reduces fixation time.
- The amount of exposure. The more exposure the film has to light, the less unused silver halide to be removed by the fixer, and hence the faster the rate of fixation.

As a general rule, a film is considered completely fixed after twice the time it takes to *clear* it. Clearing or fixation occurs when all visible traces of the silver halides (a milky appearance) have disappeared. The clearing time can be determined by taking an undeveloped piece of the same type of film and agitating the film in the fixer until it clears. This procedure can be performed under normal room lights. The tongue cut from the beginning of the 35mm film may be used for this purpose.

Life of a Fixing Bath

The useful life of a fixing bath depends on several factors. One of which is the amount of material treated in the fixing bath. You cannot state accurately the exact amount of film or paper that can be safely fixed in a given amount of fixer. It is common practice to consider the fixer exhausted when the clearing time for the film is double the time it was originally. For a fixer used solely for prints, this is not easy to determine; therefore, the life of the fixer is considered ended after a given amount of paper has passed through it. This is usually about 200 8x10 prints (or equivalent) per gallon of fixer.

Using an exhausted or near exhausted fixing bath may cause the staining of films and paper. To avoid such staining, use two fixing baths in succession is the best practice. Initially, two fresh fixing baths are used. The materials are treated in the first bath until they are just cleared; then they are transferred to the second fixing bath for an equal period of time. In time, clearing time in the first bath (which is doing most of the fixation) is doubled from the original time required when the bath was fresh. When this occurs, the first bath is removed from use and replaced by the second bath. The second fixing bath is replaced by a completely fresh solution. This process is repeated as required, so the second bath is always relatively fresh. Using this procedure ensures that all film (and photographic paper) leaves the second fixer in stable condition and does not fade with time. This method is also economical, because all fixer is used to a point beyond that at which a single bath could be used.

WASHING

An unwashed or improperly washed emulsion will stain, crystallize, and fade. Therefore, the washing of the photographic emulsion is as important as any other part of processing. Removing as much of the salt and fixer

from the emulsion is essential. Only by good washing techniques can image permanence be assured.

The purpose of washing is to remove the soluble salts from the emulsion. Fixing converts silver salts into soluble salts that must be removed. If the fixing process is incomplete, even prolonged washing cannot make the image permanent. This is because the compounds of silver sodium thiosulfate remaining in the emulsion discolor in time and produce stains. Thorough washing is necessary to remove the fixing agent that, if allowed to remain, slowly combines with the silver image to produce brownish yellow stains of silver sulfide and causes the image to fade.

Water containing iron should not be used for washing. However, impurities, such as rust, dirt, or silt, can be removed by installing a 5 micron water filter in the supply line.

Seawater may be used to wash negatives if it is followed with a freshwater rinse. Salt water removes the hypo from film in about two thirds of the time required for a freshwater wash. However, a short rinse with fresh water is required to remove the salt from the film.

Temperature, chemical contamination, and rate of water change all affect the time required to wash film correctly.

Temperature

The wash should be kept within a range of 60°F to 75°F (15.6°C to 23.9°C). Within this range of wash temperatures, the warmer the water, the shorter the washing time required. However, for black-and-white film, a wash temperature of 75°F should not be exceeded. Water at temperatures above 75°F swells the gelatin and tends to inhibit diffusion. It also can damage the emulsion. Therefore, you should keep the temperature of the wash water constant with the processing solutions.

Chemical Contamination

Adding negatives fresh from the fixer into a tank of partially washed negatives nullifies the effects of previous washing, and you must start the washing procedure again. The reason for this is that the negatives with the higher concentration of fixer add enough chemicals to the washed negatives to contaminate the partially washed film. This situation can also occur if

your hands are contaminated by chemicals when you place them in the wash tank.

Rate of Water Change

The length of washing time also depends on the diffusion of the hypo from the emulsion of the material. The rate of diffusion depends on the amount of fresh water coming into contact with the emulsion. Hypo remaining in the emulsion is continually halved in equal periods of time as the washing proceeds; for example, the average negative gives up about one half of the hypo it contains in 1 minute when in direct contact with running water. After 2 minutes, one fourth of the hypo remains, and so on, until the amount of hypo remaining eventually becomes negligible. Thus the rate of washing depends upon the degree of agitation and the amount of fresh water that comes in contact with the emulsion. The minimum washing time for negatives in running water is 20 minutes when a complete change of water occurs every 3 minutes.

Rapid film washers are designed to provide a constant freshwater exchange across the film emulsion. When rapid film washers are used, such as a Hurricane type of film washer, the film can be washed satisfactorily in 5 minutes.

WETTING AGENT

After washing, water often drains from film in an irregular manner, clinging to both emulsion and base sides in drops, streaks, and uneven patterns. When such partially drained or incompletely wiped films are subjected to hot air or radiant heat, the areas under these streaks and drops of water dry much more slowly than the surrounding film. The swollen gelatin at these points is subjected to stresses and shrinks unevenly, changing the density of the silver image. When surplus water is removed from the emulsion side and drops of water remain on the base side, drying of the emulsion immediately opposite the water spots is retarded and drying marks usually result. The use of a wetting agent helps to prevent the formation of these water spots.

Wetting agents are chemicals that “superwet” the film to promote faster and more even drying. Wetting agents are chemically different from soaps, but they perform a related function. They all lower surface tension of liquids so the film surfaces are wetted quickly and evenly. Kodak Photo-Flo is a wetting agent used in imaging facilities.

After washing, bathe the film in a 1- or 2percent solution of wetting agent (prepared according to instructions provided by the manufacturer) for about 2 minutes. Then drain the film briefly for about 30 seconds. Squeegee the film between your index and middle finger to remove surface foam and excess wetting agent. Be sure your hands are clean and dampened with the wetting solution before squeegeeing the film.

DRYING

The final step in processing is to dry the wet film. This step should be given special attention. Film drying has two distinct phases. The first is the removal of excess water from the film surfaces. The second is the drying of the film by evaporation.

When you are drying the film, the primary problems you must guard against are uneven drying, dust, scratches, and damage to the emulsion caused by overheating. Dry the film in a vertical position, hanging it from a line or beam by film clips. When you are drying roll film, curling can be avoided by hanging another film clip at the bottom of a strip of film. Sheet film should be hung from one corner of the film to prevent drying streaks. Film should not normally be dried in the hanger or reel in which it was processed, since *uneven drying results*.

Dust and water spots are the problems you encounter most frequently when drying films. When the dust is not embedded in the emulsion, you can remove it with a camel-hair brush. Embedded dust in the film requires the film to be rewashed and dried properly. Water spots are more serious, since uneven drying can cause not only white stains but also small craterlike formations in the film under each spot. The white stains can be removed with alcohol, but the craterlike spots become a permanent defect. The best cure is prevention. You can avoid these problems by keeping the film surface clean and by using a wetting agent before drying.

The photographic emulsion consists of one or more layers of gelatin with silver halides of varying sizes distributed through the layers. After exposure and development, the halides are changed to metallic silver that occupies space and does not absorb water. In an emulsion that is unexposed, the undeveloped silver salts are made soluble and are removed from the emulsion during the fixing and washing stages. Only the gelatin and the space occupied by the halides remain, and these do absorb water. Because of these conditions, dense

negatives, or negatives containing many heavily exposed areas, contain less water and dry faster than thin negatives. When you think about this for a moment, you can see that since the heavily exposed and lightly exposed areas are distributed randomly throughout the average negative, drying occurs rapidly in the dense areas, more slowly in the intermediate areas, and most slowly in the thin or unexposed areas. Obviously, then, film does not dry uniformly.

When gelatin dries, the water it contains must first migrate to the surface and then evaporate into the air. Ideally, these processes should take place simultaneously and at the same rate. However, when the surface moisture evaporates too rapidly, the surface becomes hard, and the internal moisture is unable to escape it. In addition, when drying is too rapid, the outer surface shrinks while the rest of the gelatin layer is in an expanded state. This causes strains that can have a harmful effect upon the emulsion.

For a negative to dry, it must be surrounded by dry air; that is, air that contains a lower relative percentage of moisture than the gelatin. When the heated air circulates, the damp air moves away from the surface of the wet film and replaces it with dry air that permits the drying process to continue. This is the principle behind the air impingement dryers currently in use. Heated air accepts more moisture than cool air. When the air does not move, air can become heated and rapidly reach a state of equilibrium with the moist film, and drying stops.

In an air impingement drying system, air is warmed and blown against (impinges upon) the surface of the wet film. The warm, dry air picks up moisture and moves on. It is immediately replaced by more warm, dry air, and the process continues until the film is dry. The rate of drying is controlled by adjusting the velocity, temperature, and humidity of the air in the drying chamber. In hot and humid climates where the air is saturated with moisture, the air must be passed through a dehumidifier before it enters the drying chamber. When this is not done, the film does not dry. In dry climates, you must reduce both the heat and the air velocity to prevent overdrying.

Photographic films begin drying at the corners and edges as well as in the areas of heaviest density. This introduces strains in the direction of the dry areas. As a film continues to dry, the strains gradually begin to equalize, and the film, when dried properly, ultimately lies flat. The surface is not moist to the touch, but it is firm and soft enough that flexing does not damage it. If

overdried, the film curls toward the emulsion and can become brittle.

The rate of drying and the amount of curl also depend upon how thick the emulsion layer is and whether or not the film has a gelatin backing. Naturally, the thicker the layer, the longer the drying time. A gelatin backing takes time to dry, but it introduces an opposing curl and causes the dried negative to lie quite flat.

FILM PROCESSING EQUIPMENT

Hand processing of photographic film is best carried out in a darkroom that is properly equipped. Whether the darkroom is large or small, certain essentials are necessary for good quality processing.

The darkroom must be clean and well ventilated. Shelves, bottles, racks, processing equipment, walls, and floors that are spotted with dried chemicals are harmful to photographic images. Navy photo lab equipment, therefore, must always be spotlessly clean.

The arrangement of a darkroom should be convenient, "a place for everything and everything in its place." There should be adequate and correct safelights placed at recommended working distances. Only necessary sensitized material should be in the darkroom. Temperatures in the lab should be maintained as closely as possible to the normal processing temperature—about 70°F to 75°F. The well-equipped darkroom should contain the following items: sink, graduates, required chemicals, waterproof aprons to protect clothing, clean towels, accurate thermometer and timer, and the necessary film hangers, trays, reels, and tanks. All darkrooms should be well stocked with prepared chemicals in containers that are labeled properly. In general, good photographic quality demands that all work must be conducted in a clean, orderly, and systematic manner.

DARKROOM SINKS

Sinks in the photographic darkroom should be sized adequately and constructed properly. Most sinks in Navy labs are factory-made and meet all the requirements for photographic work. Sinks should be big enough and built so they drain thoroughly. The sink should have *duckbords* to keep trays and tanks off the bottom and to permit water to circulate under and around the solution tanks to maintain correct and constant temperatures. Sinks, also, should have a mixing valve to control the temperature of the water in the sink and a

303.23

Figure 10-1.-Photographic processing sink

standpipe to hold water in the sink at the correct depth, yet still allow water to flow out (fig. 10-1).

SAFELIGHTS

The function of a safelight is to transmit the maximum amount of light that can be used safely without damaging the sensitized materials being processed. The color sensitivity of different sensitized materials varies. Therefore, the color and intensity of transmitted light must be varied accordingly. A darkroom safelight is the combination of a rated light source and a filter designated to protect a specific sensitized material.

The word *safe*, of course, is a relative term since no sensitized photographic materials are ever completely safe from the effects of safelight illumination. However, a filtered light is accepted as safe when the sensitized materials can be handled under the illumination with no evidence of fogging for at least twice as long as the normal processing time. No procedures must be followed precisely when safelights are used:

- Use only the size of incandescent bulb specified; for example, 7 1/2 watt, 15 watt, or 25 watt.

- Handle sensitized material at the distance recommended by the manufacturer. This is usually between 3 and 6 feet.

To determine whether a safelight is safe, you should follow these procedures:

1. In the dark, place a sheet of unexposed film, emulsion-side up, on the working area where the film is to be processed.

2. Place several coins on the emulsion and turn on the safelight. Leave the safelight on for twice the length of time the film will normally be processed.

3. Process the film normally and check to see whether there is less density in the areas covered by the coins. When there is less density, it indicates the film was fogged by the safelight and the safelight is not safe. A safelight that causes fogging may be corrected by replacing the filter, by installing a lower rated bulb, or

Figure 10-2.—Safelights.

303.24

by increasing the distance between the safelight and the material. Safelight filters are covered in chapter 3.

A safelight is most efficient when its output of illumination is indirect or reflected. When the safelight is not constructed on the indirect principle, it should never be pointed directly at the sensitized material; it should be placed so the light beam is away from or at an

angle to the sensitized material. Figure 10-2 shows safelights used in photographic darkrooms.

SHEET FILM HANGERS

Sheet film hangers are made of stainless steel or plastic that resist corrosion in photographic solutions

Figure 10-3.—Sheet film hangers.

Figure 10-4.—Roll film processing tank and reel.

(fig. 10-3). They are constructed of perforated metal or plastic and channeled to receive and suspend film in solution. This allows the solution to circulate freely over the film surface. Sheet film hangers are used in tank developing and their use is described later in this chapter.

ROLL FILM TANKS AND REELS

Hand processing of roll film is usually done on reels in roll film tanks. The center-feed reel and tanks used most commonly in the Navy are made of stainless steel. The film is wound onto a spiral reel. The reel is then placed into a tank for processing (fig. 10-4).

TRAYS

Trays used for processing photographic film (roll or sheet) are the same as those used for processing photographic prints. They may be made of any material that is not affected by, or cause contamination of,

photographic solutions. Most trays used today are made of stainless steel or plastic.

SHEET FILM DEVELOPING TANKS

Tanks used for developing sheet film come in a variety of shapes and sizes. They are usually made of stainless steel.

To process sheet film in tanks, load the film into sheet film hangers and then place it into the developing tanks of solutions (fig. 10-5).

FILM WASHING EQUIPMENT

Film washing does not require special equipment. Sheet film can be washed in the same type of tank or tray that is used to process the film or in tanks designed for film washing.

When a tray is used, only one film at a time should be washed. When more than one piece of film is washed at a time, the films will probably rub together and be

Figure 10-5.—Film developing tanks.

Figure 10-6.—Washing film in trays.

scratched. Only line copy types of negatives are usually washed in a tray.

The most effective washing method in a tray is when a siphon device is attached to the edge of the tray. The device siphons water from the bottom of the tray, while fresh water enters at the top (fig. 10-6). Because fixer is heavier than water, it sinks to the bottom of the tray.

The best way to wash hand-processed sheet film (especially more than one sheet at a time) is in a sheet-film washing tank. Film hangers hold individual negatives suspended separately in the tank. Fresh water flows into the bottom of the tank and runs out around the sides at or near the top of the tank (fig. 10-7). When you place the film hangers into the tank, ensure the negatives are separated, so sufficient fresh water reaches all areas of each negative.

WARNING

Aboard ship, hoses attached to potable water spigots can back siphon chemicals or wash water from the trays or sink into the drinking water supply. These hoses must have a backflow preventer installed in the plumbing system.

Figure 10-7.—Film washing tank

Figure 10-8.—Rapid roll-film washer. 237.126

A rapid roll-film washer is excellent for washing hand-processed roll film. It is a cylindrical tank, large enough to hold several spiral reels. The washers come in a variety of sizes that will wash from two 35mm reels to as many as six or eight 120 reels (fig. 10-8).

The rapid roll-film washer is constructed so the wash water enters the tank at the base and flows up

Figure 10-9.—Washing film in processing roll-film tank.

through the tank and around the film at a rapid rate. By discharging the water from the top of the tank, you can remove more hypo in a shorter time.

Roll film also can be washed in the roll-film tank in which it was processed. To wash roll film in a roll-film processing tank, simply push a small hose down into the center of the reel and have the faucet turned on, so the water overflows steadily from the tank (fig. 10-9).

TIMERS

Every darkroom should have a reliable timer. Ideally, the timer should have both a minute hand and a sweep second hand. The timer most commonly used in the Navy is a Gray Lab timer (fig. 10-10). Not only does this timer have a minute and sweep second hand but the numbers and hands are fluorescent so they can be seen in the dark. A Gray Lab timer also has an alarm (buzzer) that indicates when the time for processing is up.

PROCESSING METHODS

No matter how many rolls or sheets of film you develop, it helps when you carry out the processing in three distinct phases, beginning with preparation. First, your work area must be clean, and the equipment needed must be arranged so it is easy to locate in the dark. The second phase is processing. If you are not familiar with darkroom work, you should complete ALL the processing steps with dummy or practice film and water to substitute for processing solutions under white light and then practice a few times in the dark. The third phase is film drying.

Figure 10-10.—Gray Lab timer.

302.285

To make the latent image visible and permanent, you must process the film in different chemical solutions. There are five steps in the black-and-white processing phase. The first step is development. In this step the film is placed in a developer that transforms the latent image into a visible black metallic silver image. In the second step the developing solvents are neutralized, and development is retarded or stopped by a rinse bath or acid stop bath, respectively. The third step involves placing the film into a fixing bath to remove the light sensitive, undeveloped silver halides. The fourth step is to wash the film to remove all the chemicals, and the last step is to dry the film. Each of these steps is explained further in this chapter, since there are certain controls that must be applied to each step.

Some of the processing steps may be carried out in white light, while others *must* be done under appropriate safelight conditions or in total darkness. The steps that must be done in darkness or under suitable safelight conditions begin when the film package, holder, or roll is opened and end when the film is removed from the fixer.

As discussed earlier, there are five steps in film processing. The steps and the lighting conditions under which they are carried out are as follows:

1. Development-dark or appropriate safelight
2. Rinse or stop bath-dark or appropriate safelight

3. Fix-dark or appropriate safelight
4. Wash-white light
5. Dry-white light

In addition to exposure, there are four factors in development that control image density, contrast, and, to a limited degree, the uniformity of individual densities in a negative. These four factors are the type of developer used, development time, temperature of the developer, and agitation as follows:

- **Type of developer.** One type of developer cannot cover all film exposure/processing situations. For example, film exposed under poor lighting conditions may require a vigorous developer to bring out as much image detail as possible, while film exposed under normal conditions requires a normal working developer. There are many different developers, each provides a different activity and quality of development. The actual choice of the developer to use depends on the following: the type of film, conditions under which it was exposed, type of negative required, developing time that is best for the method of development to be used, and the manufacturer's recommendation.

- **Time and temperature.** Many factors must be considered if you want to ensure correct development during film processing. Two of these factors are the length of time the film is allowed to develop and the temperature of the developer solution. Both factors can have a significant impact on the quality of the processed film.

As explained earlier, the activity of a developer increases as its temperature increases. Film development carried out for a given time at a given temperature produces both predictable and desired results—assuming, of course, that the film has been exposed properly. When film is developed for a given time at a given temperature, it is called "time and temperature development."

In the time and temperature method of film processing, as in any method of film processing, if the film is developed for too short a time or at too low a temperature, a weak, low-contrast image results. Underdevelopment can result in insufficient highlight density. On the other hand, if the negative is developed for too long a period or at too high a temperature, the result is a negative having too much density. The developer solution overdevelops the exposed areas and may even develop some of the unexposed silver halides.

For correct development, both time and temperature must be accurately controlled. Within limits, time can

be adjusted for a given temperature, or temperature can be adjusted for a given time.

There is a definite correlation between time and temperature. When it is impossible to maintain solution temperature at the desired level, time can be shortened or lengthened to compensate. As the temperature increases, developing time must be decreased to provide equivalent development. As the temperature decreases, development time must be increased.

The normal temperature for hand processing most black-and-white film is 68°F (T-Max film with T-Max developer is 75°F). There are several reasons for this standardization. At a temperature of 68°F, the gelatin swells sufficiently to allow adequate penetration of the developing solution without oversoftening to the point where it is easily damaged (which occurs at higher temperatures). Temperatures lower than 68°F slow development excessively. Only when time is of the utmost importance are accelerated temperatures used. In most instances when high temperatures are used, the film is treated in a hardening bath before processing, or the film is designed specifically for being processed at such temperatures. Since a rise of several degrees in temperature shortens development only a small amount, there is little to be gained by deviating from standard processing temperatures.

When you know the time and temperature relationship for a given film and developer combination, processing in total darkness becomes simple. You simply adjust solutions to the prescribed temperature and then process the film for the required time. Assuming proper exposure, time and temperature processing can produce a correctly developed negative without your having to see what is happening in the solution.

All solution temperatures (developer, rinse, fix, and wash) should be as close to each other as possible. When there is considerable difference in the temperature of the solutions, excessive graininess may result, or the emulsion may be subject to excessive expansion and contraction that causes it to wrinkle or crack. This effect is called *reticulation*. Since reticulation is not correctable, it causes the negative to be useless for printing.

The temperature of solutions may be adjusted by surrounding them with hot water, cold water, or ice. Never add water or ice directly to a solution because it dilutes the developer to an unknown degree. Ice may be placed in a container and suspended in the solution. An immersion heater may be used in the solution to raise its temperature.

• **Agitation.** If a film is placed in a developer and allowed to develop without movement, the chemical action soon slows down because the developing agent in contact with the surface of the emulsion becomes exhausted and bromide (a restrainer) is released as a by-product. When the film is agitated, however, fresh solution is continually brought to the surfaces of the film, and the rate of development remains constant. Therefore, agitation also has an important effect on the degree of development. An even more important effect of agitation is it prevents uneven development. If there is no agitation, the exhausted solution that became saturated with bromide from the emulsion may flow slowly across the film from the dense highlight areas and produce streaks. Constant agitation is usually recommended for the first 30 seconds of tank development and for the entire developing time when the film is being processed in a tray. After the initial 30-second agitation cycle, the film should be agitated for 5 seconds, once every minute during the remaining time.

The time, temperature, and amount of agitation required for a film/developer combination are recommended by each manufacturer of film or developer. These recommendations are in the instructions that accompany the film or developer. Another reference source is the *Photo-Lab-Index*.

There are three different methods of processing film by hand. These are as follows: the *tray*, the *sheet-film tank*, and the *roll-film tank*. Each method is discussed here with an example of the darkroom arrangement used.

TRAY PROCESSING

The tray method is used primarily for processing only a few sheets of film. With a lot of experience, you can process as many as 6 to 12 sheets of film in a tray at one time. You will find it easier to work with only a few sheets of film at a time, and repeat the process, than to start all the sheets at the same time and damage them.

The tray processing method described here has proven satisfactory under most conditions for processing one sheet of film at a time. You should use this method as described and develop the necessary skill using this procedure before you attempt to use variations.

The trays should be considerably larger than the film being processed; for example, 4x5 film should be processed in 8x10 trays, 8x10 film in 11x14 trays, and

11x14 film in 16x20 trays. Ideally, the trays should be arranged in a shallow sink that contains temperature-controlled circulating water. The trays should be arranged with the developer to your left as you face the trays. The stop bath goes next to the developer, followed by the fixer and the wash tray.

In all Navy imaging facilities, it is standard procedure when processing film (or prints) by hand to work from left to right.

Rinse the trays with fresh water as a precaution against contamination, and prepare the solutions. When the solutions are ready, place the exposed film holder to be unloaded on a clean, dry area of the workbench near the developer. Set the timer for the correct developing time, and place it in a convenient location near the processing solutions. Then, if you are processing panchromatic film, turn out all the lights. If you are processing monochromatic or orthochromatic film, you can use a suitable safelight.

Remove one sheet of film from the holder and submerge it quickly, emulsion-side down, into the developer. Then immediately turn it over (emulsion-side up) and slide it back under the surface of the developer quickly, and agitate it vigorously to eliminate possible air bubbles. The surface of the film must be wetted quickly and evenly; otherwise, developing marks may result. Start the timer just before the film is placed into the developer.

During tray development, the tray should be rocked continuously to provide constant agitation. Be careful that the tray rocking is not too fast and that it is varied at intervals; for example, first front to back, and then side to side to avoid patterns of uneven development caused by regular waves.

CAUTION

Do not allow your fingernails to touch the film emulsion at any time.

Tray development involves constant agitation, and development time is usually about 20 percent less than if the same film were being developed with intermittent agitation. When tray agitation is done very slowly, the agitation should be considered intermittent and the developing time adjusted accordingly.

When the timer rings, remove the film from the developer, drain it from one corner, and submerge it in the stop bath. Agitate the film in the stop bath for about 5 seconds; then transfer it to the fixer. You must agitate

the film vigorously in the stop bath and initially in the fixer because gases are released in these solutions and there is danger of air bubbles forming on the film surface. If you allow these air bells, or bubbles, to form, they may cause dark spots. This is due to the continued action of the developer beneath the bubbles. Agitate the film in the fixing bath for a few seconds and then the safelights or the white lights may be turned on. Continue agitating the film until it loses the cloudy or creamy appearance. Note the time required for this change to occur because it is just half the total required fixing time. Agitate the film several times during the second half of the fixing time. After the film clears, continuous agitation is not necessary.

After fixing is completed, transfer the negative to the wash water and continue to agitate it unless a regular film washing tank or tray is available. After washing is complete, the film should be treated in a wetting agent and dried.

As stated earlier, with experience you can process several sheets of line copy film at a time in a tray. When processing several sheets in a tray at once, there is an added step. This is a predevelopment rinse in clean water that should be at the same temperature as the rest of the processing solutions. The predevelopment rinse is located to the left of the developer. Its purpose is to prevent the films from sticking together in the developer.

The procedure for processing more than one sheet of line copy film at a time is the following:

1. When the solutions are ready, place a dry, dust-free paper or cardboard on the workbench near the predevelopment rinse. Place the exposed film holders near this clean working space.

2. Set the timer.

3. Turn out the lights.

4. Remove one film from its holder and place it, emulsion-side down, on the clean paper. Remove the second film and place it, emulsion-side down, on top of the first. Continue until all the film is placed in a loose pile on the space provided for them.

5. Pick up the film on top of the pile with your left hand (keep it dry until all films have been placed in the water), drop it, emulsion-side down, into the water, and immerse it quickly with your right hand. Pick the film up immediately, turn it over, emulsion-side up, and push it back under the solution. Place the wet film, emulsion-side up, at one end of the tray. Immerse the next film in the same manner. Stack it on top of the first

film, and continue with this procedure until all the films are stacked in a pile at one end of the tray. Your left hand should follow the last film into the tray to assist in the agitation of the films.

Wet film may be handled with wet fingers. However, be extremely careful to **KEEP WET FINGERS OFF DRY FILMS**. Slight pressure with the balls of the fingers is not harmful to a wet emulsion unless it has swollen excessively.

The films should be agitated or shifted constantly to prevent the individual sheets from sticking together. Agitation is accomplished by moving the first film from the bottom of the stack and placing it on top or by starting a new stack at the other end of the tray. Continue agitating the films from bottom to top until they become completely saturated with water-about 1 or 2 minutes is sufficient. After the emulsion is completely saturated, the danger of films sticking together is no longer a problem.

6. Remove the films, one at a time, from the predevelopment rinse and immerse them in the developer. Place the films in the developer, emulsion-side up; slide them under the surface of the solution quickly, and agitate them vigorously to eliminate possible air bells. Start the timer just before the first film is placed in the developer. Use your left hand to remove all films from the water, and be careful not to get the water contaminated with developer. Your left hand should follow the last film transferred from the water into the developer to help with the agitation.

It is important for you to locate the first sheet of film placed in the developer quickly. To do this, align the long dimension of all other films at a right angle to the first sheet placed in the developer.

The films are immersed, emulsion-side up, in the developer to reduce greater damage that would occur if the emulsion, already softened by presoaking, were allowed to come in contact with the bottom of the tray. Be careful not to dig or drag the corner or edge of a film into the emulsion surface of the film below it. Do not allow your fingernails to touch the emulsion at any time. Stacking films by aligning their edges against the sides of the tray helps to reduce scratches and abrasions.

7. Agitate the films constantly, not by rocking the tray, but by moving each film from the bottom of the stack and placing it carefully on top, and pressing it down gently to assure a flow of solution over its surface. Continue this procedure until the developing time is up.

Figure 10-11.—Sheet film hangers arranged for tank processing.

237.137

8. When the timer rings, remove all the films from the developer in the same order that they were placed in the developer, and submerge them in the stop bath. Your right hand should go into the stop bath with the first film and stay there to handle each film as it is transferred from the developer by your left hand. Use your left hand only for transferring the film to avoid contamination of the developer or spotting of the film. A few drops of developer will not affect the stop bath or the fixing bath, but a few drops of either of these solutions could ruin a developing solution.

9. After all the films have been shifted several times in the stop bath, they should be transferred individually to the fixing bath or hypo. Shift the films several times in the fixing bath, agitating them vigorously. Then safelights or the white lights may be turned on. Continue shifting the films until they lose the cloudy or creamy appearance. You must shift the films several times during the second half of the fixing time, but continuous agitation is not necessary.

10. After fixing is completed, transfer the negatives to the wash water and continue agitation unless a regular film washing tank or tray is used. The negatives also may be put in regular film hangers for washing.

11. Treat the film in a wetting agent and dry it.

TANK DEVELOPING SHEET FILM

Tank development is the recommended method for hand processing of orthochromatic and panchromatic sheet film. The solutions and the tanks are deep enough to cover the films in the vertical position completely. The films are supported individually in the tanks by the film hangers. Films supported in this way are much less subject to damage. The solutions last longer when used in tanks and can process more films than when they are used in trays.

Tank development for sheet film requires tanks to hold the solutions, and racks, reels, or hangers to support the films while in the solutions. The solutions used should have good-keeping qualities, and they should be the type that can be replenished by adding fresh solution or replenisher, so the volume in the tanks can be maintained at the proper working level.

The minimum number of tanks that can be used is three: one each for developer, stop, and fixing bath. However, when a predevelopment rinse is used, four tanks are needed.

The tanks are arranged in the processing sink submerged in enough water to maintain the solutions at the prescribed processing temperature. Again the process is arranged so you work from the left to right.

The film hangers are simply channeled frames suspended below a bar. The bar is long enough to reach across the tank and allow the frame to hang below the surface of the solutions. The frame has channel pieces on the bottom and both sides and a hinged channel across its top. Each hanger holds from one to four films. The hangers accommodate standard film sizes, such as 4x5, 8x10, and so forth. After the films are loaded into the hangers, they may be carried through the entire process without being touched by the hands.

The darkroom should be checked using the steps common to all film processing, as explained earlier in this chapter. After you check the solutions and their arrangement, check the temperature of the solutions, and check the safelights. Then arrange an adequate supply of clean, dry, empty film hangers on a rack, and an empty rack to hold the loaded film hangers (fig. 10-11). If the darkroom is not equipped with racks to hold the film hangers, clean, dry tanks can be used to hold both unloaded and loaded hangers. Set the timer, place the exposed film holders between the empty film hangers and the rack or tank that is used to hold the loaded hangers, and turn out the lights.

To load a sheet film hanger, remove one of the sheet films from its *holder*. Take a *hanger* in one hand and place the thumb at one end of the hinged channel. Bush the hinged channel up and back with the thumb until the film can be slid along the inside of the end channels to the bottom of the frame. **HANDLE THE FILM BY THE EDGES ONLY.** Make sure the film is seated properly in the three channels of the hanger. When the film is seated properly in the side and bottom channels, bring the top channel forward and down over its top edge (fig. 10-12). This encloses all four sides of the film in the channeled frame. The hanger should be given a slight shake to ensure that the film is in place. Set the loaded hanger on the rack or in the empty tank to hold it.

The film should be loaded onto the hangers with the emulsion side facing you. This prevents the top channel from scratching the emulsion as the film is slid into the frame. Load the other film to be developed in the same manner. However, do not load more hangers than can be handled conveniently in the tanks at one time.

When the hangers are loaded, lift all of them by their crossbars and lower them into the predevelopment water rinse, if one is being used. They should be lowered into the tank until the hanger crossbars rest on top of the tank. The predevelopment water rinse is optional when using the tank method of development, but the water rinse has the following advantages:

Figure 10-12.—Loading a sheet film holder.

Figure 10-13.—Sheet film tank processing agitation.

- The air bubbles that usually occur when dry film is immersed in a solution can be removed without harmful effects in the predevelopment water rinse.

- When the water-softened emulsion is placed in the developer, the action of the solution begins uniformly over the entire emulsion. Thus uneven or streaky development is avoided.

- The predevelopment water rinse removes the antihalation backing dye that interferes with the action of some developers.

- The predevelopment water rinse brings the temperature of the film and the hangers to the processing temperature. Maintaining constant temperatures in all of the processing solutions is very important.

The predevelopment water rinse is given by immersing the loaded hangers in a tank of water and agitating them for about 2 minutes. The temperature of the water should be the same as that of the other processing solutions. The loaded hangers are then lifted out of the water, drained by one corner, and processed in the usual manner.

Immerse the hangers in the developer slowly and smoothly to avoid splashing or the formation of air bells. Air bubbles usually result when films are immersed rapidly, especially when a predevelopment water rinse was not used. All the hangers should be immersed simultaneously to assure uniform agitation and development.

Strike the hangers sharply against the sides of the tank several times to dislodge any air bubbles that may

Figure 10-14.—Reel processing rack.

have formed. Start the timer and agitate the film for 1 minute. After the first minute of development, agitate for 5 seconds at 1-minute intervals.

The processing tank usually has enough space for several additional hangers. However, this space is needed for proper agitation of the film hangers. Agitation should be accomplished by lifting the hangers out of the tank draining them momentarily from a different corner each time, and replacing them in the solution (fig. 10-13). Hangers should not be agitated too vigorously from side to side. This forces the developer through the holes in the hangers at high speed, causing developing trails near the holes. The objective is to assure an even flow of fresh solution over the surfaces of the films regularly according to a fixed schedule.

About 10 seconds before completion of the developing time, lift each of the hangers out of the solution, let them drain for 10 seconds, then lower them into the stop bath. Agitate them several times in the stop bath, drain them, lower them into the fixing bath, and agitate them constantly for 2 or 3 minutes.

The fixing and the washing requirements are the same as described previously in this chapter. When washing is complete, place the film hangers and film into a wetting agent; then remove each sheet from its hanger and hang it up by one corner to dry.

When the film is dried in the hangers, there is a number of drying marks along the edges of the film, thus reducing the actual usable size of the negative image. It is better to suspend each film individually from a line

Figure 10-15.—Cutting leader tab film 35mm film.

with a film clip. Dry the hangers, *after washing them in hot water*, without film in them.

With suitable racks designed to hold reels, roll film can also be processed in tanks (fig. 10-14).

TANK DEVELOPING ROLL FILM

The most convenient and reliable way to hand process roll film is in a small roll-film tank. The construction of tanks and reels differ somewhat among the various manufacturers' models, resulting in differences in loading and use. Generally, the basic unit used in Navy imaging facilities consists of a stainless steel, center feed, spiraled reel to hold the film; a tank with a lighttight cover; and a filler cap. Each reel is constructed for a specific size roll of film; for example, 35mm, 120, and 220. The tank top permits pouring the chemicals in and out of the tank under white light conditions. The tanks come in sizes to hold from one 35mm reel to as many as eight 35mm reels or five 120 reels. Small roll-film tanks of all metal construction (tanks, lids, caps) should be numbered or marked in such a way that prevents mixing different tanks, lids, and caps.

The proper loading of a film reel *in total darkness* can be the most important steps and challenges in processing roll film.

When processing roll film with a paper backing, the paper tape sealing the exposed roll should not be broken until the lights have been turned out. Also, for 35mm film, the cassette should not be opened until the lights have been turned out. If a short length of film is left protruding from the 35mm cassette when the film is rewound, you do not have to open the cassette to remove the film. The leader or loading tab on 35mm film can be cut off square while in the light to ease loading of the spiral reel (fig. 10-15).

Figure 10-16.—Leading 35mm film on wire reel.

There are three ways of loading a center-feed spiral reel. You should practice each method (with a dummy roll), both in white light and in total darkness, and select the method that is most comfortable for you. Then perfect that method. Although the three methods are similar, there are differences that may make one method easier for you. However, before beginning one of these methods, make sure that both the reel and your hands are clean and dry.

- First method. Remove the film from the cassette (35mm) or separate it from the paper backing (120 or 220). The film must be handled only by the edges to prevent scratches and fingerprints. (When you work

with 35mm film, the tongue of the leader must be cut off to make a square end before loading the reel.)

If you are right-handed, the ends of the wire spiral must be positioned on the top and pointing to the right (fig. 10-16, view A). For left-handed people, the ends of the wire spiral reel when positioned at the top must point to the left.

Next, bow the film slightly concave to clear the edges of the spiral and clip or hold the film to the core (center) of the reel (fig. 10-16, view B). The film emulsion must face in or toward the reel center. The tension on the film should be firm enough to prevent the film from skipping the spiral grooves, but not so firm it overlaps or falls into the same groove twice.

Turn the reel, apply gentle pressure, and keep your thumb and forefinger on the film edges. This pressure produces a slight curl in the film and allows it to pass onto the edges of the reel. As you continue to turn the reel, the film straightens out and fits into the grooved spaces in the reel (fig. 10-16, view C). Apply enough tension to the film so it does not skip grooves. However, too much tension may cause the film to overlap in the same grooves of the reel.

- Second method. Prepare the film as before. Hold the reel to be loaded on a clean working surface in your left hand with the ends of the wire spiral at the top, pointing toward the right (fig. 10-17, view A). If you are left-handed, hold the reel in your right hand with the ends of the spiral wires at the top, pointing toward the left.

Hold the film by its edges in your right hand and bow it between your thumb and forefinger. With your left index finger or thumb, depress the grip clip and gently push the end of the film into the core of the reel (fig. 10-17, view B). When the reel does not have a grip clip, insert the film end about 1/4 to 1/2 inch into the reel core and hold it there with your left thumb and index finger (if right-handed). Remember, always load the reel with the film emulsion facing in, or toward, the reel core. Be sure the film is held straight at the reel center (fig. 10-17, view C).

Now turn the reel smoothly in a counterclockwise direction with your left hand, and guide the film into the spiral grooves with the thumb and forefinger of your right hand (fig. 10-17, view D).

- Third method. Slowly unwind the paper backing from the film until you feel the film with your finger. Do not completely unwind the paper backing from the film.

Figure 10-17.—Loading 120 film on reel.

302.286

For 35mm film, if the film was not completely rewound into the cassette, cut the tongue off and leave the film in the cassette.

Hold the reel to be loaded in your left hand with the spiral wire ends at the top, pointing toward the right. Allow about 3 more inches of the paper backing to unroll. Bow the film and place it straight into the reel core. Smoothly and slowly turn the reel counterclockwise, guiding the film onto the reel. Allow the paper backing to unwind as the film is wound onto the reel.

When all but about 3 inches of the film is on the reel, you will feel the end of the film taped to the paper backing. With 35mm film in a cassette, the film stops unrolling from the cassette when the end is reached.

When you feel the tape or the end of the film is about 3 inches from the reel, carefully separate the film from the paper backing or cut the 35mm film right next to the cassette, being careful not to pull the film from the reel. Finish loading the reel.

The paper backing on 220 roll film does not run the full length of the film as does 120 film. The paper backing on 220 film serves as a leader and tailer that are taped to the ends of the film. Therefore, when using the third method described above, you must remove the paper tailer from the film before loading the reel.

Before processing film using a reel, you must practice loading it by using a roll of practice film in white light, then repeating the procedure in total darkness until you feel comfortable and do not damage the film. Only after you have the reel(s) loaded properly, should you think seriously about processing.

When a roll-film tank is used to process fewer rolls of film than the tank can hold, you must take up the extra space in the tank with enough empty reels to fill the tank. The empty reels go into the tank on top of the reels holding the film. When you are pouring solutions into the tank, completely cover ALL the reels in the tank.

When processing with a roll-film tank that has a lighttight cap, you can add or dump the chemicals without removing the cover. Only one tank is needed because the required solutions are poured out of and into the tank through the tank cover during processing. This can be done in white light. The chemicals should be arranged in the darkroom sink from left to right (developer, stop bath, etc.) and be

Figure 10-18.—Arrangement of materials for processing film.

brought to the correct processing temperature in a water bath (fig. 10-18).

A clean, dry area should be provided on the work counter for loading the film onto the reels. The following steps are used to process roll film in small tanks:

1. Load the reel or reels with the film to be processed.

2. Place the loaded reels into the tank. If the loaded reels do not come to the top of the tank, add empty reels to take up the space. Place the cover and cap on the tank. The lights may now be turned back on. Once the lights are on and before the film is fixed, be careful not to remove the tank cover or the film will be exposed to light and ruined.

3. Hold the tank in one hand and tilt it slightly; pour the developer directly from the graduate into the tank through the light trap pouring hole. Pour as fast as you can without spilling. As the developer nears the top of the tank, hold the tank level or set it in the sink. Fill the tank to just overflowing. This step should take about 10 to 20 seconds, depending on the tank size.

4. Once the tank is full, immediately start the timer, replace the cap, and strike the tank on the edge of the sink once or twice to dislodge any air bubbles. Now agitate the film by inverting the tank slowly end to end (fig. 10-19). The initial agitation should be 30 seconds. Place the tank in the sink on its bottom (cover up).

5. Once every minute, agitate the film for 5 seconds by slowly inverting the tank end to end. After

each agitation cycle, place the tank back in the sink. If you are holding the tank during the entire developing period, the heat from your hands may heat the developer and produce unpredictable results.

6. When only 10 seconds of developing time remain, remove the *cap* from the tank cover. Immediately start pouring the developer out of the tank through the light trap pouring hole. Dump the chemicals according to local instructions of the imaging facility. This step should take about 10 seconds to complete.

7. When the developer has been emptied from the tank, fill the tank to overflowing with stop bath. The stop bath must be poured into the tank through the light trap pouring hole in the tank cover. Replace the cover cap. Agitate the film in the stop bath for about 30 seconds using the end-for-end method.

8. When the stop bath portion of the process is complete, pour the stop bath through the light trap pouring hole in the tank cover.

9. With the tank cover still in place, pour fixer into the tank and replace the cap. Dislodge the air bubbles and set the timer to the required fixing time. Start the timer and agitate the film using the same agitation as the developer.

10. When the prescribed fixing time has elapsed, remove the tank cover and pour the fixer from the tank back into the bottle from which it came. Never pour the

Figure 10-19.—Agitation of a small tank.

303.41

fixer into the sink. The fixer can be reused and then later saved for silver recovery.

11. The film can be washed either in the tank or in a roll-film washer. When the tank is used, insert a hose down through the center of the reels until it is about 1/2 inch from the bottom of the tank. Adjust the water (at the same temperature the film was processed) so a steady overflow is created. Wash the film for about 20 minutes. When you use a rapid roll-film washer, again, adjust the water temperature and place the reels containing the processed film into the washer. Adjust the rate of water flow until the reels start to turn. When the reels start to turn, adjust the rate of water flow until the reels stop turning. Set the timer and wash the film for about 5 minutes.

12. While the film is washing, rinse the processing tank, tank cover, and cap with clean water. Fill the tank with water (check the temperature) and add the wetting agent. After the film has been washed, place the film, still on the reels, into the wetting agent solution. Replace the tank cover and cap and agitate the film in the wetting solution very S-L-O-W-L-Y for 1 minute.

13. After 1 minute in the wetting solution, remove the loaded film reels from the tank. (Do not save the wetting solution.)

14. To dry the film, attach the end of the film to a film clip in the drying cabinet. Let the film unwind from the reel as you slowly lower the reel.

When the film is unwound, depress the grip clip (if the reel has one) or remove the film from the core of the reel. Squeegee the film and attach a second film clip to the lower end of the film. Close the drying cabinet door and dry the film.

Photographer's Data Sheets

Sometimes a photographer's data sheet will accompany film that enters your imaging facility to be processed. The photographer's data sheet will provide you with information on how the film was shot, lighting conditions, and specific processing instructions. When a photographer's data sheet accompanies the film or job order, you should process the materials specified by the form.

Cleaning Up

After processing, the darkroom and all equipment must be cleaned up immediately. Rinse thoroughly all processing equipment: tanks, reels, hangers, thermometers, funnels, and so forth, in clean, warm water. Place the clean equipment where it can dry before it is needed for the next processing run. Always keep the processing room shipshape.

REVERSAL PROCESSING

Normal processing of black-and-white film produces a negative; from this negative, a positive is made. However, by using the *reversal process*, you can produce a positive image directly on the black-and-white film.

In the reversal process, a negative image is first obtained by developing the original latent image in a developer that contains a silver halide solvent. This developer dissolves some of the excess silver halides. After leaving the developer, the *negative* image is dissolved away in a bleach bath. The silver halides remaining are chemically “exposed” (fogged) and developed by a second developer that provides the positive image.

Not all black-and-white films reverse well. Films that reverse well are Kodak Direct Positive Panchromatic Film 5246 (35mm), T-max 100 Direct Positive Film, and Kodak Technical Pan Films (35mm). Instructions for reversal processing of these films can be found in the *Photo-Lab-Index*.

COLOR PROCESSING

Color adds realism to photographs. At one time color was difficult to work with. It required special cameras and specialized films that could be processed only by the manufacturer of the film. Now, color materials have been improved and are used extensively in the Navy. They are far more popular than black and white.

As discussed in chapter 2, color films have at least three emulsion layers. Primary colors affect one emulsion layer only, while complementary colors affect two emulsion layers; for example, the color cyan affects the blue and green sensitive layers. White light affects all three emulsion layers. Black has no effect on any layer. The type of process used depends on whether the film is a negative type of film or a reversal (slide) film. The most common processes used in the Navy are Kodak Flexicolor for color negatives and Kodak Process E-6 for color reversal films. The Eastman Kodak Company continually strives to improve their processes by making them more environmentally safe. Always consult the *Photo-Lab-Index* for the most current information concerning film and paper processes.

COLOR NEGATIVE PROCESSING

In negative color film, the dye couplers produced are complimentary to the primary colors of light; therefore, a blue light records as yellow, a green light records as magenta, and a red light records as cyan. All colors within a scene are recorded through varying combinations of these yellow, magenta, and cyan dyes. The color negative is a halfway stage to a color print.

The cyan and magenta dye image layers formed by color processing absorb some light wavelengths that should be transmitted. In negative color film, these absorbed wavelengths of light cause a color cast when printed. To prevent this color shift, the manufacturer has given the green and red sensitive emulsion layers a yellowish and pinkish tint, respectively, during manufacturing. These tints are what form the overall orange mask that you see in finished color negatives. Some color film used for aerial photography does not have this orange mask. This allows for a direct interpretation of the negative image. An orange-masking filter is added when these films are printed.

The Kodak Flexicolor process is used for processing color negative films and some monochrome film, such as Ilford XP2. There are four chemical steps and two wash cycles in the Flexicolor process. They are

as follows: color developer, bleach, wash, fix, wash, and stabilizer.

Color Developer

The first step in color negative processing is color development. A color developer in color processes works nearly the same as a black-and-white developer. The exposed silver is developed by a developing agent and converted to metallic silver and by-products are released. As the color developer is working at developing the silver, it becomes oxidized and reacts with nearby dye couplers. Dye couplers are built into the emulsion around all of the metallic silver sites. The primary function of a color developer is to develop the exposed silver halide crystals to metallic silver and then form dye around the metallic silver, using the oxidized color developing agent.

Temperature of the color developer is the most critical of all the processing steps. The temperature of the color developer must be $100^{\circ}\text{F} \pm 0.25^{\circ}\text{F}$ ($37.8^{\circ}\text{C} \pm 0.15^{\circ}\text{C}$). All other wet steps in the process can be within the range of 75°F to 105°F (24°C to 41°C); however, it is best to maintain all solutions at constant temperatures.

Bleach

Bleach is found in all color processes. The purpose of the bleach is to take the metallic silver still in the color film (or paper) and convert it to a form that can be fixed. In color products, all of the silver must be removed. Only the color dyes form the image. The bleach chemically converts the silver metal back to a soluble silver halide.

Fixer

The function of fixer is the same in color processes as it is in black-and-white processes. A fixer converts the silver halide to a water soluble form. Most fixers use thiosulfate as the fixing agent in an acidic solution. When fixing is incomplete, unwanted silver remains in the image. This causes a loss in contrast, added density, and an unwanted color cast.

Stabilizer

The final wet step in color negative film processing is the stabilizer. The main purpose of this solution is to provide a wetting agent to prevent spotting of the film and to prevent unused magenta dye couplers from attacking the newly formed magenta dye.

Unlike black-and-white film processing, color negative film cannot be “push processed” successfully; therefore, you must choose a film with an appropriate film speed for the lighting conditions in which you photograph your subject.

COLOR REVERSAL FILM PROCESSING

Color transparency film forms dyes according to a reversed silver positive; for example, a yellow dye image forms in the top emulsion that corresponds to an absence of blue in the original scene. This yellow dye subtracts blue light. A blue image is formed by magenta dye (minus green) and cyan dye (minus red), thus leaving blue. In color transparency film, the dyes subtractively produce a correct color positive image of the scene photographed.

The Kodak E-6 Process is used in the Navy for processing color reversal film. There are seven chemical steps and two wash cycles in the Kodak E-6 Process. They are as follows: first developer, wash, reversal bath, color developer, prebleach, bleach, fixer, wash, and final rinse.

The first chemical step is the first developer. The first developer is a black-and-white developer that converts the exposed latent image in each emulsion layer to a metallic silver. Like black-and-white negative processing, after the film leaves the first developer, there are undeveloped areas where the silver halides are unaffected by camera exposure. It is these undeveloped areas that the final color positive images are formed in reversal film.

After the first developer, the film is chemically fogged or “re-exposed” in the reversal bath. The reversal bath exposes the silver halides that were not developed in the first developer. This re-exposure is what forms the positive image. After 1 minute in the reversal bath, the normal room lights can be turned on.

After fogging, the film is developed in a color developer. The color developer works the same way in color reversal processing as it does in color negative processing. It changes the fogged silver halides to black metallic silver and at the same time, cyan, magenta, and yellow dye couplers are formed by the exhausted developer.

At this stage the film looks completely black because the formed dyes are shielded by the developed silver. The film is then placed in a prebleach. The prebleach prepares the film for the bleach and also stabilizes the dye layers.

The metallic silver is removed by the bleach and fixer processes. The bleach and fixer work the same way as they do for color negative processing. After the silver is removed, only the dyes remain, forming the image.

The film is then washed to rinse away any remaining chemistry and soluble silver. The last chemical step in the E-6 process is the final rinse. Final rinse provides a wetting agent to aid in uniform drying.

It is possible to “push process” (underexpose and overdevelop) or “pull process” (overexpose and underdevelop) most color reversal film; however, some sacrifice in quality results in “push processing.” Less detail in the shadow areas (weaker blacks), less exposure latitude, and noticeably increased grain occur when color reversal film is “push processed.” When the film speed is altered, only the first developer time is changed. All other chemical steps remain the same. You should not exceed two f/stops when you intend on “push” or “pull” processing.

MACHINE PROCESSING

Today most film processing is performed by machine, especially in larger imaging facilities. Machine processing has many advantages compared to hand processing. Machines can process high-volume production more efficiently and more consistently compared to hand processing. When machines are used, the variables involved in processing can be controlled more easily. Time, temperature, and agitation can be kept constant if the machine is properly maintained and operated properly. With fully automatic processing machines, all you must do is feed the film or paper into the machine and retrieve the finished product.

When there are advantages, there are also disadvantages to machine processing. Machines require maintenance, can jam, occupy precious shipboard space, and may require special plumbing, ventilation, or power requirements. The need for proper maintenance is most critical. Poor equipment maintenance is probably the major cause of machine processing problems. Therefore, it is very important for scheduled preventive maintenance to be performed properly on all imaging equipment, especially automatic processors. The best images captured by a camera are not of any use if they are not processed correctly and without defects. You must be qualified completely in the Planned Maintenance System (PMS) to become a valuable member of an imaging facility.

In a high-volume production facility, the advantages of automation far outweigh the disadvantages. There are

302.287

Figure 10-20.—Image Maker processor.

numerous automatic processors available on the market today. Two types of machine processors are commonly used in Navy imaging facilities. They are the rotary drum and the roller transport type of processors.

ROTARY DRUM PROCESSOR

The semiautomatic processor most commonly used in Navy imaging facilities is the Image Maker, manufactured by the King Concept Corporation (fig. 10-20). When this type of processor is used, film and paper are processed in a lighttight canister. Before being processed, the material must first be loaded on stainless steel reels for roll film or in a plastic basket for sheet film or paper. Depending on the setup of the processor, the holding tanks are either filled with chemicals manually, or they may be filled automatically. The solutions are then automatically added to and dumped from the processing drum. The time, temperature, and solution steps are all controlled by a computer. After the material is processed, it is then removed from the drum, squeegeed, and dried.

The advantages of a rotary drum processor is it is of relatively low cost, small in size, and can run many different processes through the same machine. The major disadvantage is that the chemicals are dumped

instead of replenished which is not environmentally sound and can be costly.

ROLLER TRANSPORT PROCESSOR

Automatic processors commonly use roller transport systems (fig. 10-21). When you are using these machines, the material being processed moves at a constant speed by friction. The materials are guided through the processing solutions by a series of rollers and rack assemblies. On many processors, a leader tab must be attached to the beginning of the roll to aid in pulling the film through the machine.

The size of the solution tanks and the length of the path through the solution determine how long the material must remain in each solution (processing time). On some automatic processors, the finished, dried, processed material leaves the processor and is then automatically cut and sorted.

Roller transport processors contain two major sections: the wet section and the dryer section. The wet section contains the developer, fixer, and wash tanks. The film is then transported through a squeegee assembly and enters the dryer.

Many different types of processors are used throughout the Navy. Each type has specific installation,

Figure 10-21.—Roller transport processor.

operation, and maintenance instructions supplied with it. Therefore, in this section only general information that applies basically to any machine processor is discussed.

TRANSPORT SPEED

Most black-and-white automatic film processors have a variable speed operation. Unlike hand processing where developing time is measured in minutes and seconds, machine processing developing times are measured in feet-per-minute (fpm). Both methods measure the length of time the material is affected by the developer and other solutions. Most color processors have a set machine speed that can only be adjusted slightly because color materials must be processed to specific parameters so processing cannot be manipulated.

The time the solutions are allowed to act on the film or paper is a result of the speed that the machine moves the sensitized material and the length of time the material is immersed in a particular tank. Most machines have an fpm indicator that shows the set speed of the processor. The temperatures of solutions and the specific number of feet in each section of the machine are usually constant factors. It is the rate the paper or film travels that determines the total processing time; for example, if the speed is set to 10 fpm and the total roller

path in the developing tank is 30 feet, a certain point on the material being developed takes 3 minutes ($30 \div 10$).

Regardless of the machine speed, film or paper cannot be processed faster than the total required solution times. For example, you are processing film that requires a processing and drying time of 10 minutes and 20 seconds. When the machine is processing this film, it takes 10 minutes and 20 seconds before the first foot of film leaves the dryer. However, the total time to process the entire roll is related to the speed of the machine and the total length of the material. For example, if the machine speed is 10 fpm and the roll is 10 feet long, the film takes 10 minutes, 20 seconds, plus 1 minute ($10 \div 10$). With a 200-foot roll, access time is 10 minutes, plus 20 seconds, plus 20 minutes ($200 \div 10$), or a total of 30 minutes, 20 seconds. It is important for you to know the access time of the processor. When the material being processed does not exit the machine in the required time, a machine malfunction or jam is evident.

WATER TEMPERATURE AND FLOW RATE

Wash water is an important processing consideration. Not only is the water temperature important but also the flow rate of the water. Two factors that must be considered are as follows: sufficient flow to ensure

complete washing of the material and to control or eliminate waste.

If the wash-water temperature is allowed to drop to 65°F (18°C) or below, emulsion staining may result. As the temperature decreases, less emulsion swelling occurs, reducing the effective penetration of fresh water supplied to the emulsion. When the emulsion does not swell, the chemical-laden water does not get out through the emulsion surface. These retained chemicals can cause stains.

The wash water flow rate is another important factor to consider. This rate must be high enough to wash the material, but no more. When insufficient water flow is supplied to the machine, crystallized chemicals may be seen on the material, and additional staining can result. You must not adjust the water flow rate higher than is needed. A few extra gallons-per-minute flow rate may not seem important; however, over time this effect can be extremely costly, particularly aboard ship.

SOLUTION TEMPERATURE

In machine processing, the temperature may vary, depending on the machine and the kind of processing being performed. High-speed processing machines operate at higher solution temperatures. Temperature control is critical and must be maintained to produce correct results. Although this may be considered a variable factor, the temperature is controlled automatically by processing machines. In some machines, the solution tanks are immersed in a temperature-controlled water jacket. By controlling the water temperature within the water jacket, you can control the temperature of the solutions inside the tanks. In other machines, the solution temperature is directly controlled by separate heaters or heat exchange control units in the recirculation system. A temperature probe in the solution tank monitors and controls the temperature control unit.

SOLUTION LEVELS

The solution levels of a processor must be checked before processing material. If the solution level is too low, stains, improper tracking, and roller marks may affect the film or paper. When the machines are shut down for a period of time, some evaporation occurs. Since only the water from the solution evaporates, you must top off the solution tanks with water before processing material. There is a certain amount of carry-over of solution from one tank to another within the machine. Usually, chemical carry-over is minimized

with roller squeegees. When the replenishment rate of the processor is set properly, this carry-over is compensated by supplying fresh chemistry to the solution tanks.

REPLENISHMENT

Most processing machines use relatively large quantities of solutions to carry out the process properly. However, even considering the large quantities involved, certain chemical components within a given solution are used up at varying rates. In addition, there are certain reactions that form by-products that build up in the tank of the processor; for example, bromide (a restrainer) gradually builds up in the developing solution. Also, there is a certain amount of carry-over of solutions from one tank to another. This causes a continuous change in solution strength and solution purity. The replenisher solution replaces the used chemicals, dilutes the excess chemicals or by-products that have built up, and replaces the solution lost by carry-over and evaporation.

The replenishment system used in machine processing is called the *bleed* method. When the bleed system is used, a calculated amount of replenisher solution is added and forces some of the used solution out through an overflow drain in the solution tank. You must check the established replenishment rates as well as the replenisher holding tanks before and during processing. Inconsistent results occur when the process is not replenished correctly.

DRYER TEMPERATURE

After the material is processed and washed, it continues through the machine into the drying cabinet where moisture is removed. The drying cabinet is more than a heated compartment for the processed material. In a majority of machines, both the temperature and the humidity of the cabinet are carefully controlled. Too little drying causes the emulsion to be tacky, whereas too much drying may produce excessive curl and brittleness. Brittleness, once it occurs, cannot be eliminated; so it must be prevented. Both the temperature and the relative humidity must be adjusted for the speed of the machine and the type of material being dried.

Under ideal conditions, the drying cycle should yield a stable 50 percent relative air humidity. To lower the relative humidity of air, you must heat the air; this accelerates the evaporation of moisture. The rate of evaporation and the relative humidity are directly

proportional to the temperature. When the temperature is too low, evaporation is slowed down. When it is too high, the emulsion may be damaged.

Roller transport processors provide very consistent processing results and can be converted easily to a new process. The disadvantages of roller transport processors are: they can leave scratches and scuffs from dirty rollers touching the film, they require a high amount of maintenance due to the large number of moving parts, and oxidation can be a problem due to the churning action of the rollers in the chemistry.

QUALITY PROCESSING

The processing required to produce a quality product of any particular film varies with different developer and film combinations, time and temperature of the process, agitation, the film exposure, and the skill of the darkroom worker. A good, high-quality image is one that is free from all processing faults, including scratches and dirt, and so forth.

When processing black-and-white film, your goal is to produce a “normal” negative that is as fault-free as possible. Normal is a rather vague term; however, a normal negative is one that yields a pleasing print or reproduction of the original scene when printed without a printing filter or with a No. 2 printing filter.

When film is exposed and processed properly, it is a normal negative. However, when a negative varies from normal, you should be able to determine what conditions caused the deviation.

A negative has several *basic* characteristics to consider when evaluating quality. These basic characteristics are as follows:

- General negative density or opacity to light.
- Image highlights or areas of greatest density.
- The shadows or areas of least density.
- Contrast or the differences between highlight and shadow densities.
- Tonal gradation or the range of grays between the highlights and the shadows.
- Graininess or the appearance of silver grains in a negative that have clumped together. The size of the clumps determines the degree of graininess in the processed material.

All the basic characteristics of a negative are affected to some extent by a combination of exposure

and development. By studying these characteristics, you can usually determine the cause of an error or poor quality in a negative.

DENSITY

Density determines how much of the incident light falling upon a negative passes through the image. When a small amount of silver is present in the negative, the image appears thin (transparent), and it has low density. When there is a large amount of silver present, only a small amount of light passes through the image, and the negative is said to have high density.

A low density, thin negative can be caused by underexposure or underdevelopment or by a combination of the two. A heavy or dense negative is the result of either overexposure or overdevelopment or a combination of the two.

HIGHLIGHTS

The highlights, or dark areas, of a negative for most purposes should not lack detail. When detail is lacking because the highlights are too dark, the highlights are too dense or blocked up. Excessive highlight density is caused by overexposure and/or overdevelopment. When both the highlights and the shadow areas are too thin and lack detail, the negative is probably underexposed. Thin highlights are caused by underexposure and/or underdevelopment.

This may seem like a repetition of the previous discussion on density. However, a negative could and may have *overall* good density except in the highlight areas. This situation is a result of exposure latitude that is not great enough for the scene brightness range.

SHADOWS

The shadows, or the more clear areas of the negative, also should contain image detail. If these areas are so thin and weak that they are transparent or nearly so, the shadow areas are said to be lacking in detail. Loss of shadow detail is caused normally by underexposure.

The need for detail in both the highlights and the shadows for photographs of most subjects cannot be stressed too strongly. One is as important as the other in the production of good photographs.

CONTRAST

Contrast is the difference in density between the highlights and the shadows in a negative. When this

difference is great, the negative is said to be contrasty. When the density difference is small, the negative is said to be flat or lacking in contrast.

For a negative to have normal contrast, the density differences between the highlight and shadow areas of the negative must be proportional to the reflective brightness range of the subject photographed

A contrasty negative usually is the result of overdevelopment but also may be caused by a high scene lighting ratio (a contrasty original scene). A flat negative, on the other hand, may be caused, primarily, by underdevelopment or a low-contrast original scene.

TONAL GRADATION

Photographers often concentrate on the density and detail of highlights and shadows when they should actually be considering the most important or middle tones of the negative. Middle tones are the various tones of gray between the highlights and the shadows; that is, the densities that are not highlights or shadows are termed middle tones or intermediate tones. The middle tones vary with the type of film and the subject contrast. A negative should have a range of middle tone densities that correspond proportionally to the middle reflective brightness of the subject. A panchromatic negative that does not have proportionate midtones is contrasty or flat.

GRAININESS

Because photographic images made from film are made up of fine silver grains, the images may appear “grainy” or exhibit graininess (fig. 10-22).

All negatives show graininess to some extent. The most important factors affecting negative graininess are as follows:

- The composition of the emulsion or the inherent graininess of the emulsion. That is to say, the size of the grains used to produce the emulsion.
- The type of developer used. When fine grain is desired, a fine-grain developer with the appropriate film should be used.
- The extent of development. Overdevelopment is a major cause of excessive graininess.
- Exposure or negative density. Overexposure is another key contributor to graininess. As negative density increases, so does graininess.

Figure 10-22.—Grain structures in emulsions.

- Image sharpness. The sharper the film image, the greater the image detail and the less apparent the graininess.

EFFECTS OF EXPOSURE AND DEVELOPMENT VARIATIONS

The nine negatives reproduced in figure 10-23 compare the effects of exposure and development variations. From the left, they show the effects of development; from the top, they show the effects of exposure. The center negative has been given both correct exposure and normal development and is a “normal” negative that will print without a filter or with a No. 2 filter.

Negatives 1, 4, and 7 have been underdeveloped, while 3, 6 and 9 have been overdeveloped.

The negatives across the top-1, 2, and 3-are underexposed and lack detail in the shadow areas. Increasing development (No. 3) had no appreciable effect on the lack of shadow detail. Little can be done to improve negative quality when exposure is insufficient. Underexposure is identified by lack of shadow detail.

The negatives across the center-4, 5, and 6-were given correct exposure and all have sufficient shadow detail. However, No. 4 was underdeveloped and is flat or lacks adequate contrast. Negative No. 5 received normal development, has good shadow detail, and good contrast. It is a “normal” negative. Negative No. 6, although having received correct exposure, was overdeveloped. This resulted in excessive highlight density with a loss of highlight detail and excessive contrast. The highlights in both 6 and 9 are too dense.

Negatives 3, 6, and 9 are all overdeveloped. The correctly exposed negative, No. 6, is so dense that almost no detail is visible in the highlights. The highlights of the overexposed and overdeveloped negative, No. 9, are completely blocked up.

When a correctly exposed film is given normal development as in negative No. 5, the negative has

Figure 10-23.—Exposure and processing affects.

303.43

clearly defined detail in all parts of the image from the strongest highlights to the weakest shadows. The contrast is satisfactory. It may not reproduce the contrast of the original scene exactly, but it has sufficient contrast to produce a pleasing reproduction.

When the film is overexposed and normally developed, as in No. 8, the highlights in the image show a loss of detail. Giving the overexposed film less than

normal development may save some highlight detail, but it also reduces the contrast. When the overexposed film is overdeveloped, as No. 9 was, all highlight detail is destroyed and the contrast is also reduced.

Table 10-1 is a listing of defects that commonly occur in film processing. The appearance, the cause, and the remedy for each of the defects listed are also provided.

Table 10-1.—Negative Defects: Their Appearance, Cause, and Remedy

Defect	Appearance	Cause	Remedy
Abrasion marks or streaks.	Fine black lines, usually resembling pencil scratches and running in the same direction.	Friction on emulsion caused by improper handling or storage. Dirt, or grime, in camera or magazine.	Great care should be taken in storage of film. Boxes containing film should be stored on end, so no pressure is exerted on the surface of the emulsion. Care, also, should be taken not to rub or drag sensitized material over a rough surface. Be sure camera back or magazine is clean and free from dirt, or grime.
Air bubbles.	An air bubble occurring during development shows as a small, transparent spot. Sometimes minute dark streaks lead from the spot. When the negative is rocked in a tray, streaks project from each side of the spot in the direction the tray was rocked. If the tray is rocked in two directions, streaks form a cross with a transparent spot in the center. In tank development, dark streaks usually form at the lower edge of the transparent spot. In the fixing bath they show as small, round, dark spots.	Transparent spots occurring in the developer are caused by bubbles of air on the surface of the emulsion. These prevent the developer from coming into contact with the emulsion. Darkened streaks are the result of excess oxidation of the developer, caused by air in a bubble. Dark spots that occur in the fixing bath are caused by a pocket of air holding the fixer away from the emulsion and allowing a slight continuation of development.	Immerse film carefully and thoroughly in developing and fixing solutions. Move film during development and fixation to break up and prevent air bells. Water always contains some air and when there is a rise in temperature, air is expelled and gathers in the form of small bubbles on the inside of the tank and also on the surface of the film during preliminary stages of development.

Table 10-1.—Negative Defects: Their Appearance, Cause, and Remedy-Continued

Defect	Appearance	Cause	Remedy
Blisters.	They resemble the familiar ones that are caused by slight burns on human skin.	Liquid or gas formed between the emulsion and film support when the solution has become too warm and has loosened the gelatin from its support. Also, produced by developer and fixer being too strongly concentrated. Changing film from one bath to the next may cause the formation of gas between the emulsion and support. Frequently caused by taking the film from an alkali solution and placing it into a strong acid. Another common cause is allowing water from a faucet to flow directly on the emulsion.	Blisters can be avoided by eliminating their causes.
Brown spots.	Small brown- or sepia-colored areas or spots on the negative.	Produced by oxidized developer or by fine particles of chemicals settling on the film before development. May also occur during washing, from rust, and other impurities in the water.	Avoid exhausted or oxidized developer. Keep processing room clean and free from dry chemicals. Filter the wash water.
Crystalline surface.	Surface of the negative emulsion has a crystalline appearance, resembling frost on a windowpane.	Insufficient washing after fixing. Hypo remains in the film and crystallizes.	Increase the final wash time.
Dark lines.	These lines are divided into two distinct classes. The first class, those that run from dark areas to more transparent areas of the negative, and the second class, those that run from the more transparent areas to the darker areas. In both cases, lines are wider, not as clean cut, and not nearly as parallel as abrasion marks.	The first class is caused by insufficient agitation of the negative in tank development. Cause of the second class is thought to be of an electrolytic origin.	For the first class, more frequent agitation during development. The remedy for this class aggravates the defect in the second class. Only known remedy is to remove all film hangers from the tank four or five times during the developing period, holding the hangers in a bunch, and allowing the corners of the hangers to rest on the edge of the developing tank for 10 to 15 seconds.

Table 10-1.—Negative Defects Their Appearance, Cause, and Remedy-Continued

Defect	Appearance	Cause	Remedy
Fading tendency.	Sepia- or yellow-colored stains or areas in the negative.	Incomplete fixation or insufficient washing causes fading. Remnants of the fixing bath left in the emulsion continues its action, and in time, this defect appears.	Properly fix and wash negatives.
Fingermarks.	Imprint of fingers shows up on negative.	Impressing wet or greasy fingers on the emulsion of film before or during development and fixation. If mark is merely an outline of the finger, it was caused by water or grease on the finger; if dark, it was caused by developer; if transparent or light, it was caused by fixer.	Keep hands clean and dry when handling film. Sometimes natural oil on the fingertips causes grease marks. When fingers become wet with water or solutions, wash and dry thoroughly before attempting to handle film.
Fog (Aerial).	A slight veiling of the negative or parts of the negative.	Negative exposed to air during development. Occurs most frequently in freshly mixed developers.	
Fog (Dichroic).	Usually a fog of little density, consisting of finely divided particles of silver. When viewed by transmitted light, it is pinkish; when viewed by reflected light, it appears reddish green.	Hypo or excessive amount of sulfite in the developer.	Removed by treating the negative in a weak solution of potassium permanganate. Further prevention through use of clean tanks for developer and fixer.
Frilling.	Edges of the gelatin become detached from the base. Detached edge of emulsion may either break off or fold over.	Careless handling; using solutions that are too warm; insufficient hardening of emulsion due to insufficient fixation; exhausted fixing bath or one containing insufficient amount of hardener; or excessive washing. Frilling is usually caused by a combination of careless handling and any other mistake that will render the emulsion or film soft.	Handle film carefully and sparingly; use working solutions that are mixed correctly and are at the proper temperature. Wash film sufficiently, but never excessively.

Table 10-1.—Negative Defects Their Appearance, Cause, and Remedy—Continued

Defect	Appearance	Cause	Remedy
Air bubbles.	Minute pimples or blisters.	Develop by transferring the negative from strongly concentrated developer to strongly acid fixing bath without thoroughly rinsing after removing it from the developer and before immersing it in the fixing bath. In warm weather, air bubbles may appear even when using solution of normal strength, if rinsing between development and fixation has been insufficient.	Use an acid stop bath.
Pitmarks.	Fine holes or pits in emulsion.	Excessive alum in fixing bath; sulfurous precipitation from fixing bath when negatives are fixed in a tray; and film being dried too rapidly.	Proper fixing and drying.
Pinholes.	Minute transparent spots.	Dust on film before exposure.	Proper handling of film. Clean camera back or film holders before use.
Reticulation.	Leatherlike graininess or wrinkling of the emulsion.	Too great of a difference in the temperature of baths or between final wash water and the air in which the negative is dried. Gelatin may become badly swollen due to the temperature of a solution or wash water, and upon shrinking, contracts irregularly due to the metallic silver incorporated in the emulsion. Excessive softening of the emulsion followed by a strong hardening bath, or an alkaline treatment followed by strong acid.	Keep all solutions at the same temperature. Reticulation effect may sometimes be removed by placing the negative in a 10-percent solution of formaldehyde for a few minutes and then drying it rapidly with heat. Use ample ventilation when drying negatives treated in formaldehyde.

Table 10-1.-Negative Defects: Their Appearance, Cause, and Remedy-Continued

Defect	Appearance	Cause	Remedy
Streaks.	Streaks and patches. In the case of spots, may be dark, white, or transparent.	May be due to uneven development, caused by insufficient agitation. May also be due to developer splashed on the film before development, a dirty tank, fixer tray or tank used for developing, or a light fog. If the edges of the film are clear, trouble is in the camera; if the edges are fogged, it is due to a light leak in the film magazine or processing tank. Certain types of resinous woods and varnishes cause dark patches. White or transparent patches may be due to obstructions in the camera that prevented light from acting on the film; an oil or grease that prevented action of the developer; hypo on film before development. Drying marks in the form of teardrops or white patches are caused by splashes of water on a dry negative or by leaving spots of water on the film before drying, especially if the film is dried in warm air.	Trace the cause of the streaks. In many cases, they can be avoided in the operation and maintenance of equipment. When drying negatives, be sure to use wetting agent or stabilizer.

PROCESS MONITORING

To consistently produce the highest quality photographic products possible and to prevent chemical processing defects, you must monitor the photographic processes. From a hand-processing system to a sophisticated, computerized processing system, process monitoring is necessary to achieve high quality on a consistent basis. When it is performed routinely, process monitoring can detect minor problems before a major casualty to your imagery results as well as aid in the proper replenishment of your processing system.

The area of quality control and process monitoring can be very complex. Some Navy Photographer's Mates earn an NEC and specialize in the field of quality control for photographic processes. It is not the intention of this training manual to provide you with the information necessary to become a specialist in photographic quality

control; however, you must learn the appropriate steps to monitor the process.

The production of high-quality photographic products requires control over all the factors that affect light-sensitive materials. Film exposure and processing are the most important of these factors. Negatives or positives that have not been uniformly and correctly exposed and processed may provide unusable results. By monitoring the process and providing high-quality products, you can save time and operating costs by reducing waste and retakes.

Any monitoring system for the photographic process requires a reference or standard, and comparison of daily production to this standard. Visual comparison of the reference to the standard is very subjective and limited in accuracy because of personal opinion. A more accurate method is to measure your production against the standard. Two means of making

Courtesy of EG&G, Inc.
302.288X

Figure 10-24.—EG&G sensitometer.

these measurements are through sensitometry and densitometry. When sensitometry and densitometry are used, variations from the standard and the corrections recommended are expressed in numbers, not in terms of personal opinion.

SENSITOMETRY

Sensitometry is the science of determining the photographic characteristics of light-sensitive materials. In sensitometry, special test or control strips are prepared by accurately exposing the material with varying amounts of light. These test strips are then processed.

A *sensitometer* is an instrument used to produce the special test strips called sensitometric strips. A sensitometer is used to produce these sensitometric strips because it provides consistent and repeatable exposures of a known quantity and quality of light. The sensitometer is used to expose a strip of film with varying amounts of known exposure on the same strip of film. Since the sensitometer provides repeatable exposures each time, any changes in density indicates a change in processing. In Navy photography, the sensitometer is used to expose black-and-white materials only. There are several uses for sensitometric

strips; but in this training manual, we are only concerned with monitoring a process. Here the sensitometric strips are used as control strips. Control strips are made and processed under the controlled conditions of time, temperature, and agitation. This is true for both black-and-white and color materials. Black-and-white control strips are usually made in the photo lab, while color control strips are obtained by the manufacturer of each material.

Ideally, a sensitometer should be designed so you can accomplish the following objectives:

1. Predetermine the total amount of exposure.
2. Determine the difference in exposures given to various areas.
3. Control the color quality of the light.
4. Consistently reproduce or duplicate the same lighting conditions.
5. Provide a wide range of exposures.

The sensitometer used most commonly in the Navy today is the Egerton, Germeshausen, and Grier (EG&G) sensitometer (fig. 10-24). This sensitometer uses a

Figure 10-25.—Step tablets.

daylight balanced xenon flashtube. It can also produce exposure times from 1/100 to 1/10,000 second.

Step Tablets

A sensitometer is set up to make only one exposure. In order to provide a range of exposures, a step tablet is placed between the light source and the light-sensitive material. The step tablet is a strip of neutral-density filters in equal increments, ranging from 0.05 to 3.05. This range provides a 10 f/stop range. The most common step tablets are as follows (fig. 10-25):

1. 21-step tablet-1/2 f/stop between each increment.
2. 11-step tablet-1 full f/stop between each increment.

Courtesy of X-Rite, Inc.
302.339X

Figure 10-26.—Densitometer with both transmission and reflection capabilities.

Control Strips

A sensitometric control strip should be processed as a minimum-at the beginning of a production day (or shift), before any production is processed, and before shutdown. You should process a control strip just before an important mission, or a special-interest film is processed.

To expose and process a control strip, you should take the following steps:

1. Take the film (in a lighttight container) and place it next to the sensitometer.
2. Turn on the sensitometer and allow it to warm up for a minimum of 15 seconds.
3. Turn off the room lights.
4. Place the film emulsion-side down on the sensitometer and lower the platen to make your exposure.
5. When hand processing or using a rotary tube type of processor, load the control strip on the reel. When machine processing, replace the film in a lighttight container. Turn on the room lights and turn off the sensitometer.
6. When a roller transport processor is used, check the speed, temperatures, and the proper operation of all systems.
7. Stick the film into the processor so the lightly exposed end of the film enters the machine first. When hand processing or using a rotary tube type of processor, process normally.

302.290

Figure 10-27.—Control strips read from center of each step with emulsion facing up.

DENSITOMETRY

A densitometer is an instrument used for measuring and reading the density of film and paper directly. Film is read on a transmission densitometer, and paper is read on a reflection densitometer. Most densitometers supplied by the Navy today have both transmission and reflection reading capabilities on the same meter (fig. 10-26).

A densitometer uses a photoelectric cell to measure the light transmitted through film or reflected from paper electronically. Before a densitometer can be used, it must be checked and calibrated against a reference standard. To use the meter, you must place the material to be measured, emulsion-side up, in the light beam between the source and the photocell. The density reading is then read directly from the meter.

There are several sets of filters incorporated in the head of the densitometer. When you are reading black-and-white materials, the yellow filter must be in place. When color materials are read, there are two different sets of filters that are used. They are Status A and Status M filters. Status A filters are used to read color transparencies and prints. Status M is used to read color negative film that has an orange mask

Only certain steps of the control strip are read. The steps that you are required to read are established by the manufacturer of the material or are established by the quality control technician within your imaging facility. When you are reading the steps on your control strip, be sure that the emulsion side is facing up and take the reading from the center area of each step (fig. 10-27).

PROCESS CONTROL CHARTS

A process control chart provides a visual representation of a process. Control strips that are processed and read on a densitometer are then plotted on a control chart. The points plotted on the graph indicate what has occurred in the process at the time the control strip was processed. Through the use of control charts, a determination can be made whether the process is operating normally. As stated before, only selected steps of a control strip are monitored. For black-and-white film, the minimum steps monitored are as follows: base plus fog (B + F) or gross fog, high density, low density, speed point, and contrast.

For each step monitored on a control chart, there are three lines. The center line represents the mean (\bar{X}) (pronounced "bar X"), or average, a top line that represents the upper control limit (UCL), and a bottom line that represents the lower control limit (LCL).

Figure 10-28.—Process control chart.

Refer to figure 10-28. For example purposes only, the following steps are monitored and plotted on a control chart below. The steps being monitored are as follows:

- High density (HD) is step 17 and reads 1.20.
- ◆ Low density (LD) is step 6 and reads 0.60.
- ◆ Speed point (SP) is step 4 and reads 0.23.
- B+F is 0.12.

When plotting a control strip, you should always annotate the date and the time the control strip was processed. When all points plot within the upper and lower control limits, the film can be processed. When any point plots outside the upper control limit (UCL) or lower control limit (LCL), the process is out of control. You should notify your supervisor before processing any material through that particular process.

CHAPTER 11

BLACK-AND-WHITE PRINTING

In photography, printing is the term used to describe the process of making positive images from negatives (and in some instances, from film positives). The most familiar example is the print made on a paper base. A photographic print is made by passing light through the negative onto a piece of paper coated with a light-sensitive emulsion, very similar to film.

The two primary methods of making photographic prints are **contact printing** and **projection printing**. The principal difference in the two methods is the method of exposing the paper. In contact printing, the paper is physically in contact with the negative; while in projection printing, the paper is separated from the negative, and the image of the negative is projected onto the paper by a lens. Because projection printing is usually used to produce an enlarged image, it is generally referred to as enlarging. Contact printing produces positive images that are the same size as the negative images. Enlarging usually produces positive images that are larger than the negative image; however, because optics are used in projection printing, the image formed on the paper can also be made smaller or the same size as the negative image.

The quality of the photograph can be varied during printing through the choice of printing material, exposure, and processing. In printing, some negative defects may be compensated for, thereby eliminating the reproduction of the defect in the print.

A well-planned, black-and-white or print room should have at least the following material and equipment arranged properly so the flow of work moves easily from one stage to another:

- A contact and/or projection printer (enlarger)
- A sink large enough to accommodate the largest trays used in the print room
- Safelights
- A set of print trays
- A graduate
- A thermometer
- Print tongs

- A wall clock with a second hand
- Hand towels

Photographic printing papers are predominantly blue and green sensitive and may be processed under the appropriate safelight conditions. Consult the data sheet packaged with the paper you are using or the *Photo-Lab-Index* for the recommended safelight.

A minimum of three trays are needed for hand processing prints. The trays should be arranged in the sink from left to right—one each for developer, stop bath, and fixing bath. The ideal setup has five trays—one each for developer, stop bath, first fixer, second fixer, and a water rinse. This setup saves chemicals and results in better fixing of prints.

The chemistry used to develop and fix prints is similar to and serves the same purposes as film processing. When processing conditions are controlled carefully, the processing specifications recommended by manufacturers for their printing papers can be used to provide excellent and consistent results.

The print developer used most commonly in Navy imaging facilities is the Ilford Multigrade developer. The recommended tray processing developing times vary with the type of paper and developer being used. With the developer at 68°F, resin-coated paper development is complete in about 2 minutes. The image appears in about 30 seconds. Because developer is incorporated in the paper, the useful capacity of 1 gallon of Ilford Multigrade developer (diluted 1:9) is about 400 8x10 prints, or equivalent.

Any standard stop bath serves sufficiently. A stop bath may be used at all times, but it is necessary when processing a large number of prints; furthermore, the use of a stop bath after development prolongs the life of the fixing bath. If no acid is available for a stop bath, a water rinse should be used after the developer.

A standard fixing bath should be used to fix the prints. Consult the *Photo-Lab-Index* for the various prepared chemicals available for fixing prints. Follow the manufacturer's instructions when fixing prints because there are adverse effects in over-fixation as well as underfixation. Overfixation tends to produce thinning

303.46

Figure 11-1.—Proof printer.

or bleaching of the photographic image. Underfixation causes the image to darken with time.

WARNING

Never dump fixer down the drain. Dispose of all chemicals according to the local instructions of your imaging facility.

In this chapter, the procedures and techniques for producing black-and-white positive paper prints from black-and-white negatives are discussed. Keep in mind that the procedures and techniques provided are the basics for printing color negatives and positives to produce color prints as well as making duplicate black-and-white film positives.

CONTACT PRINTING

A contact print is produced when you expose a sheet of photographic printing paper through a negative with the paper emulsion and the emulsion side of the negative in contact with each other. Light is directed through the negative which controls the amount of light transmitted to the paper. The dense areas of the negative pass less

light than do the more clear or less dense areas. The image densities formed (after development) in the emulsion of the paper make a positive print that represents the tonal values of the original subject. Since the paper is in direct contact with the negative, the print produced is exactly the same image size as the negative.

When you are making a print from a negative by this method, only a 1:1 ratio is obtainable, but contact printing is generally a more rapid means of making prints than enlarging.

The quality of contact prints usually surpasses that of enlargements because there is no scattering of the image-forming light; however, with the ever-increasing use of small film format sizes and since only same-size prints can be made by contacting, enlarging has, for the most part, replaced contact printing in the Navy except for making proof prints.

CONTACT PRINTERS

Contact printing is the quickest, simplest, and most economical method of producing photographic prints. For making proof prints and small volume printing, all a “contact printer” needs is a sheet of glass, a light

Figure 11-2.—Contact printing arrangement.

source, and some sort of padding. For large volume and fine printing control, a specially designed and constructed contact printer is used

Glass and Pad

For you to make contact proof sheets and an occasional contact print job, only a glass and a supporting pad are necessary. “Contact printers,” consisting of a sheet of glass hinged to a metal frame and a pad assembly, are generally known as proof printers (fig. 11-1). When such a device is not available or is not large enough for the negatives to be contact printed, a piece of 1/4-inch plate glass and soft padding (such as a rubber typewriter pad) can be used. Quarter-inch plate glass is heavy enough to keep the negatives and paper flat and in contact during exposure. The glass must be free of flaws, scratches, bubbles, and dirt. For color contact printing, the glass should be water white or crystal grade; otherwise, filtration is required to overcome the color tint of the glass. The edges of the glass should be beveled and the corners slightly rounded or taped. This is a safety measure to prevent cuts when the glass is being handled.

The pad should be at least as large as the glass. The pad provides a cushioned surface to press the paper and negative together under pressure from the glass.

To use either the proof printer or the glass and pad to make contact prints, you should place the printing paper emulsion side up on the pad material. The negatives are then placed emulsion side down on the paper and the glass is positioned on top. Then turn on

303.47

Figure 11-3.—Using an enlarger as a light source for contact printing.

the exposing light (fig. 11-2). This, of course, is done in the darkroom under suitable safelight illumination.

Adequate pressure must be kept on the negative and print paper so their entire surfaces are in contact during the exposure. Any separation between the negative and the paper results in an unsharp point in the image.

The light source may be any controlled lamp for printing with a proof printer or glass and pad. An overhanging light bulb or a safelight, with the filter removed, connected to a timer is a convenient arrangement. In most Navy imaging facility print rooms, an enlarger is used as the light source (fig. 11-3).

Contact Printer

For large volume contact printing, a contact printer is more convenient. A contact printer is basically a box with exposing lights, safelights, and viewing lights inside with a glass top. It has a hinged pressure cover to hold the negative and paper in contact during exposure. Switches on the printer control the lights in the printer or the printer may have a built-in timer. Also, the contact printer may be connected to an external timer.

Contact printers are all built around the same basic idea. However, consult the manufacturer’s instructions

that accompany the contact printer for specific operating instructions.

A useful feature on contact printers is an adjustable masking device. This device is attached to the printer so it fits snugly over the printing glass. The mask consists of thin metal leaves used to “frame” the negative. These blades make it possible for the prints to have white borders or margins. To produce prints with white borders when using printers that are not equipped with a masking device, you can use hand-cut masks from thin, black paper.

The basic steps necessary for you to produce a print when using a contact printer are as follows:

- Place the negative emulsion side up on the printing glass.
- Place the paper emulsion side down over the negative.
- Bring the platen or pressure cover down into the printing position.
- Turn the printing light(s) on for the required exposure time.
- Release the platen, and process the paper.

When you are viewing the negative under a white light, it has a shiny side and a dull side. The shiny side is the film base; the dull side is the emulsion side. A similar examination of photographic paper under a safelight shows that the paper has a shiny side and a dull side. In this case, the shiny side is the emulsion side; the dull side is the paper support. Photographic paper normally has a slight curl toward the emulsion side, although this is not true in all cases.

To make contact prints, you must place the dull side of the negative in contact with the shiny side of the paper; that is, they must be emulsion to emulsion. If the negative base is in contact with the paper emulsion, the photograph will be reversed. In some cases, such a reversal in the print is not easily seen, but it becomes strikingly clear when there are letters or numbers in the picture.

CONTACT PRINTING PROCEDURE

Check the lamp to be sure it is operating properly. Rinse the trays with fresh water, and prepare the developing, stop bath, and fixing solutions. The trays should be larger than the prints to be produced, and one of the largest or deepest trays available should be used for the fixing bath.

303.48
Figure 11-4.—Black tape used as paper stops.

When the solutions are ready, rinse and dry your hands. A supply of printing paper should be available and conveniently located near the printer. Place an empty paper box or paper safe near the printer if the prints are not to be processed after each is exposed. Hold the paper in the paper box or paper safe until the paper is ready to be processed. If the paper is not stored in a paper box or paper safe, it will eventually fog even under safelight conditions.

Masking the Negative

When contact prints require white borders, some type of mask is needed to prevent the printing light from exposing the edges of the printing paper. When the printer is not equipped with a masking device, make a mask to fit the negative. (Usually proof prints do not require masking.) The material used for masks should be opaque and not much thicker than typing paper. When the masking material is too thick it causes a distinct blurring along the edges of the print image.

Some type of guideline or paper stop is useful when placed at one end and one side of the mask opening. The paper stop forms a square-corner guide for alignment of the printing paper. The paper guide helps you to place the paper evenly and parallel with the opening in the mask, and it helps keep the borders even on the print (fig. 11-4). The corner guide or stops can be quite thick without causing poor contact between the negative and the printing paper during exposure. Some printers are equipped with metal strips, so you can mask the negatives by setting the strips to frame the negative.

The negative and printing glass must be cleaned before you place the negative on the printer. Place the negative emulsion-side up on the printing glass and arrange them under the mask until the desired composition is obtained. When you must make more than one print from the same negative, tape the negative (at the corners only) to the printing glass. If the negative is completely taped down, air can be trapped between it and the glass. When the platen or pressure cover is moved into the printing position, the air does not escape. This results in an unsharp print. When you use a hand-cut mask, tape the mask to the glass along one edge before positioning the negative.

Printing Filter Selection

The first requirement for you to make a good print is a clean negative. The negative must then be examined to determine the contrast (flat, normal, or contrasty) and the approximate exposure time required to produce a quality print. As a beginning darkroom worker, you may not be able to make these determinations accurately; however, in a short time and with a little experience, you should overcome any trouble.

In analyzing a negative to determine the most suitable printing filter, be careful not to confuse contrast with density. When in doubt, make test prints. If the test print is contrasty, you should make another test print with a lower numbered filter to lower the contrast. If the original test print lacks contrast, change to a filter with a higher number to increase the contrast. This is a good time to review the information on printing filters and printing papers in chapters 2 and 3.

Test Print

The printing exposure is the operation most likely to cause trouble for an inexperienced darkroom technician. Unlike most films that can tolerate some overexposure and underexposure and still yield usable photographs, printing papers must be exposed correctly to produce good prints.

Experience and familiarity with printing equipment does help; but for a beginner, the correct exposure for prints from most negatives is best determined by making test prints.

The factors that affect exposure are as follows:

- The intensity of the printing lights
- The distance between the printing lights and the printing glass

- The sensitivity of the printing paper
- The density of the negative

The first three factors are standardized and, therefore, eliminated as variables by using the contact printer and by printing with the same type of paper. The only remaining variable is negative density. You can determine negative density by making a few test exposures. The exposure time for a negative of average density may be about 1 to 3 seconds. When the negative is large, avoid the expensive and wasteful temptation of using a whole sheet of paper; instead, use a strip about 2 inches wide and as long as the negative for the test exposure. For example, an 8x10 sheet of paper can be cut into three or four small strips.

After you have determined the filter and the test-exposure time, set the timer accordingly. Place the paper test strip over the negative in the printing position. Place the test strip on the negative so the test exposure includes some highlights, midtones, and shadow areas. Hold the paper in position with one hand and lower the platen. As soon as the platen grips the edge of the paper, move your hand away. When the platen is fully lowered, turn on the printing lights for the test-exposure time.

When the test strip has been exposed, develop it for the recommended time. If the image is too dark, the exposure was too long. If the image is too light, the exposure was too short.

It is difficult for even an experienced photographer to judge the contrast of an under- or overexposed print that has been under or overexposed. Before attempting to judge the contrast of a print, you must change the exposure until the proper density is reached. A normally exposed print develops gradually, but steadily—shadows first, then midtones, and finally highlights. The image should appear in about 30 seconds, providing the developer is at the proper strength and temperature. If the image develops very quickly with a general mottling, it is overexposed and the next test should be given less exposure. An overexposed print develops in a very short time, and the common temptation is to “pull” (remove) it from the developer. This prevents the image from getting too dark, but results in a flat, muddy, uneven, tone image. On the other hand, when the recommended development does not produce a print of the proper density after 2 minutes, the print is underexposed. After you have successfully exposed and processed a few prints, you will rapidly gain enough experience to estimate, closely, the density of negatives for contact printing exposures.

PH2 Noel R. Guest
303.49

Figure 11-5.—A processed test strip used to determine exposure.

When a change in exposure time does not produce a print of good contrast, a different printing filter is needed. When a properly exposed and developed test print lacks clean highlights and shadows, try a higher number of printing filter. When the print is mainly black and white with few middle tones, use a lower number filter. Once you have produced a satisfactory test print, you can make the production prints from that negative.

If you use a printing frame (glass and pad or proof printer) to make contact prints, the most convenient and economical way to determine exposure and correct contrast is to expose the test strip in progressive steps of say 2, 4, 6, and 8 seconds. You do this by holding an opaque card on top of the glass and covering three quarters of the paper and exposing one quarter of the paper for 2 seconds. Then move the card to cover one half of the paper and give it an additional exposure of 2 seconds. Move the card so it covers one quarter of the paper and give it another 2 seconds of exposure. Finally, remove the card and give the entire sheet one last exposure of 2 seconds. This shows a distinct progression of exposures of 2, 4, 6, and 8 seconds (fig. 11-5). Develop the test strip normally. To determine the correct exposure, you must examine the test print under white light.

When the correct exposure appears to be between two steps, the required exposure can usually be estimated with some accuracy; however, additional test prints may be needed.

After the exposure time and contrast for one negative have been determined by tests, other negatives of similar density and contrast can be given the same filtration and exposure as a starting point. At first, negatives with widely differing contrast and density require test prints. With experience, you can judge most negatives without resorting to test prints.

Exposing and Processing Prints

When a test print develops in the recommended time, rinse it in the stop bath, immerse it in the fixing bath for about 30 seconds, rinse it in fresh water, and inspect it carefully under white light. When the density and contrast of the image look correct under white light, make your first “straight print.”

Place the sheet of printing paper, emulsion-side down, over the negative in the printing position by aligning the edges of the paper with the paper stops on the mask (if a mask is used). With one hand, hold the paper in the printing position with one hand to keep it

from slipping out of place when the platen first presses against the edge of the paper, and start the printing cycle as described previously. After the printing cycle is completed, remove the paper for processing. Any number of duplicate prints can be made by repeating the printing cycle.

Drop the print, emulsion-side down, into the developer. Immerse it immediately with a quick sliding motion while pushing the print under the surface of the solution. Grasp one edge of the print, lift it up, and turn it over. Replace the print emulsion up on the surface of the solution. Push the print under the surface again and leave it under during the remaining time in the developing tray. The print must be immersed rapidly and evenly to prevent air bubbles from forming on the emulsion surface. Be sure that all the emulsion gets wet with the developer in the shortest time. Agitate the print constantly for the remaining developing time.

Each type of printing paper has its own working characteristic. The main difference in each type is the length of time required for the image to develop in a given type and strength of developer. A correct print is one that develops to the proper density and contrast in the recommended time. A print should be exposed so it reaches the proper density and contrast only with full development; otherwise, the tone and appearance of the print will be below acceptable standards. If the exposure is insufficient, the image does not develop to the desired density even with longer developing time. It appears pale and lacking in brilliance. Also, stains may occur when development is carried out too long. Paper developers work more rapidly than those used for films; consequently, print immersion must be quick and even, and agitation should be constant.

When the print is fully developed, lift it out of the developer, drain it momentarily, and place it in the stop bath. After about 5 seconds in the stop bath, lift the print, drain it briefly, and place it in the fixing bath. Agitate it in the fixing bath for a few seconds and examine it for defects that might cause it to be discarded. When the inspection is completed, place it emulsion-side down in the fixer and complete the fixing process. Follow the manufacturer's instructions as to the required fixing time. Fixing for Ilford Multigrade paper is complete after about 30 seconds in fresh fixer.

Some papers have a tendency to float in the fixing bath, especially if the bath is mixed a little stronger than usual. When prints float in the fixer, they should be handled constantly or turned facedown to prevent the emulsion from being exposed to the air. The parts of a

print exposed to the air during fixing may become stained

Prints that float facedown should not create problems except for the chance that air bubbles can be trapped under the prints. Air bubbles under a print produce stains and must be prevented. By immersing the prints edgewise and facedown, you eliminate air bubbles.

CAUTION

Never attempt to work backwards through the sink-line process. A few drops of fixer on your hands or from a print will contaminate the developer.

Group Print Development

Several prints can be processed at one time, provided they are separated and agitated sufficiently during the process. Each entire print must be wetted uniformly by the solutions so all parts of each print are processed uniformly.

When you are processing several prints at one time, immerse them in the developer separately at regular intervals and, at the end of the proper developing time, remove the prints in the same order and at the same regular intervals. To prevent the prints from sticking together, you should let each one be completely immersed before the next print is put in the developer. Agitation should be done by rotating the prints in the solution. To do this, take each print, in turn, from the bottom of the tray and place it on top of the other prints.

As the prints reach full development, transfer them one by one to the stop bath. Treat them for 10 to 20 seconds; then place them in the fixer and agitate each print to make sure none of them stick together.

After the prints are fixed, they must be washed and dried. The RC or polyethylene coating on paper prevents absorption; therefore, they require a short wash time. Wash prints for 2 minutes in a good supply of running water to ensure they are completely free of chemicals. The water temperature should not be lower than 41°F (5°C). Prints may be dried in a print dryer designed for polyethylene or RC papers not to exceed 190°F (68°C). Adjust the print dryer to the minimum temperature required to dry the paper sufficiently. If the print dryer is too hot, the polyethylene coating on the paper will melt. When a paper dryer is not available, remove the excess water and dry the prints naturally at room

*Courtesy of Ilford Photo
302.307X*

Figure 11-6.—Ilford 2150 black-and-white paper processor.

temperature. The prints should be dry in 10 to 15 minutes.

In the Navy today, most imaging facilities process prints through automatic processors (fig. 11-6). It is important for you to know how to process black-and-white prints in trays, because not all of the small facilities have automatic machines. Like all machines, automatic processors breakdown and require maintenance periodically.

When processing photographic prints through an automatic processor, you feed the unprocessed print into the machine; and within seconds, it exits the processor washed and dried. Your hands never get wet, and you can process a large number of prints rapidly. The two most common black-and-white print processors used in the Navy are manufactured by Ilford and Kodak.

When contact printing an entire roll of negatives that are not consistent in exposure, it is necessary for you to make more than one proof sheet from the same set of negatives. Each sheet of paper should be exposed to print some of the negatives correctly on that roll. The result is a composite proof sheet where all the frames are readable. After all, a proof sheet is a tool to select the best frames for enlargement and delivery to the requester. The proof sheets can be stapled together for

filing. This is why, as a photographer, you should strive to expose each and every photograph correctly. Amateur snapshooters can shoot film with wildly varying exposures; professional photographers cannot. A good print shows detail in both the highlights and the shadows.

Cleanliness is essential to produce good prints consistently. Keep a supply of clean towels handy, and wash and dry your hands before handling paper and negatives. Clean, dry fingers should touch only the extreme edges of the emulsion side of these papers. When developer is on your hands, dark fingerprints show on the print. Fixer produces white fingerprints. These fingerprints develop and show clearly on the finished prints. You should use two print tongs—one for the developer and one for the stop and fixing baths.

It is not economical to use minimum quantities of developer. Small quantities oxidize (turn brown) very quickly. Oxidized solutions cannot produce clean, brilliant, pleasing photographs.

PROJECTION PRINTING

Projection printing is the process of making positive prints by projecting the negative image onto photosensitive paper. The projected image may be

enlarged the same size as the negative image or reduced in size. When the print images are larger than the negative images, the process is called enlarging. When the print images are smaller than the negative images, the process is called reducing. Because projection printing is usually used to make positive prints with images larger than the negative, projection printers are referred to as enlargers. The term enlarging generally refers to all forms of projection printing.

Projection printing differs from contact printing because the negative is separated from the paper, and the image is projected by a lens onto the sensitized material. The negative is placed between an enclosed light source and a lens. The lens receives the light that passed through the negative and projects the image onto the paper. Changing the distance between the lens and the paper controls the size of the image. The image is focused on the paper by adjusting the distance between the negative and the lens. You can enlarge or reduce the size of the projected image by changing and adjusting these distances.

Enlarging is a very adaptable and versatile process, because considerable image and exposure control can be used. The main advantage of enlarging over contact printing is large prints can be made, but there are several other important advantages. The advantages of projection printing are as follows:

- Cropping or selecting the main area of interest in a negative can be enlarged to any suitable size. This provides an opportunity for you to eliminate unwanted and distracting elements from around the point of interest of the picture.
- Dodging or burning in. This allows you to apply local exposure control to bring out more detail in the highlight and shadow areas.
- Local fogging with a small external light, such as a penlight, to darken selected areas; for example, by darkening the background of a portrait, you direct the viewer's attention to the face.
- Special effects can be performed, such as changing the appearance of the image by use of diffusers or patterns between the lens and paper.
- Image distortion correction or introduction can be done by tilting the enlarger easel. (An easel is the device used to hold the paper during exposure.)

Figure 11-7.—Basic enlarger.

ENLARGERS

In general, all enlargers are similar in design and operation. They have an enclosed light source, some method of providing an even distribution of light over the negative, a negative carrier, a lens, a means of adjusting the lens-to-negative and lens-to-paper distances (fig. 11-7). The degree to which the image is enlarged can be referred to in terms of diameters; for example, a two diameter or 2X enlargement is twice the length and twice the width of the negative image, or four times the area. A three diameter or 3X enlargement is three times the length and width of the negative image, or nine times the area.

Most enlargers have a tungsten lamp as a light source. The lamp is enclosed in a lighttight housing that is ventilated to prevent excessive lamp heat from damaging the negative. Some enlargers have blowers to circulate air and cool the inside of the lamp housing.

The negative carrier used in an enlarger may be either a dustless type or a glass sandwich type. The dustless type of carrier is made of two metal plates with an opening in the center large enough to hold the negative. The negative is placed between these plates and held in position by its edges. This type of carrier is good for negatives 4x5 or smaller, since these negatives are stiff enough to remain flat. The glass sandwich type

Figure 11-8.—Condenser enlarger.

of carrier is a holder where the negative is placed between two sheets of glass. This type of holder is used for larger negatives since they have a tendency to sag in the center when they are not supported by glass.

The lens used in an enlarger should have an angle of field large enough to cover the negative being printed. A lens with a focal length approximately equal to the diagonal of the largest negative to be printed provides sufficient angle of field.

The bellows of an enlarger should be capable of extending at least twice the focal length of the lens. This amount of bellows extension is necessary for making 1:1 reproductions. Although it is possible to make reductions to any desired size, the bellows on most enlargers cannot be extended far enough to make reductions smaller than 1:1. Smaller reductions can be made by using a longer focal-length lens, but a better method is to use a reducing attachment. A reducing attachment consists of a section of supplementary bellows fitted with a longer focal-length lens.

The systems used to distribute the light evenly over the negative divide enlargers into three general types—condenser, diffusion, and condenser-diffusion enlargers.

CONDENSER ENLARGERS

A condenser enlarger has a set of condensing lenses between the light source and the negative. The condensing lenses concentrate or focus the light from a light bulb and direct the light rays straight through the negative to the lens (fig. 11-8).

Figure 11-9.—Diffusion enlarger.

The condenser lenses are a pair of planoconvex lenses mounted as a unit with their convex surfaces face to face. A condenser enlarger produces a sharp, brilliant image and produces higher contrast and detail than diffusion enlargers. Negative defects and scratches are more apparent in the print when made on a condenser enlarger.

The characteristics of a condenser enlarger are as follows:

- It produces maximum tone separation.
- It is suitable for making prints to a high degree of enlargement, because of its optical characteristics.
- It produces a higher image contrast with a given negative than printing with a diffusion enlarger.
- It is not recommended for negatives that have been retouched, because the edges and ridges of the retouched areas may print as dark lines.
- It may be used to emphasize negative defects and silver grain structure.

DIFFUSION ENLARGERS

A diffusion enlarger has a diffusion screen (usually ground or optical glass) between the light source and the negative. Light from the lamp, as well as the light reflected from the reflector of the lamp housing, falls on the diffuser that scatters the light. After the light passes through the diffuser, it travels in many directions when it falls upon the negative (fig. 11-9).

When a diffusion enlarger is used, negative defects are not recorded as clearly in the print, compared to condenser enlargers. There is an apparent overall “softening” of the image sharpness and a reduction in image contrast.

Most of your negatives can be enlarged equally well with either a condenser or diffusion enlarger; however, for certain work the choice of enlarger may be an important factor.

The characteristics of a diffusion enlarger are as follows:

- It should be used for printing negatives that have been retouched.
- ◆ It subdues negative defects and grain.
- ◆ It has less image contrast than that produced with a condenser enlarger.
- ◆ It is not suitable for making large prints due to the softness of the image produced.

Diffusion enlargers should be considered for use in portraiture and when the negatives have been retouched.

CONDENSER-DIFFUSION ENLARGERS

A condenser-diffusion enlarger or semidiffusion enlarger is a compromise between the two extremes of condenser and diffusion. A condenser-diffusion enlarger uses a diffusion (frosted) bulb and condensers, or a diffusion bulb with either a diffusing glass over the condensers, or else one of the condensers itself acts as the diffuser.

A condenser-diffusion enlarger has the advantages of a diffusion enlarger to reduce the effects of negative defects, silver grain structure and dust, and it also uses the condenser system for speed and uniformity of light.

The enlargers in general use by most Navy imaging facilities are the condenser-diffusion type. They use frosted or diffusion bulbs with or without a diffusion screen placed above the condensers.

ENLARGER LENSES

As with a camera, the lens of the enlarger is the heart and should be high quality and reasonably fast. It is senseless to buy high-quality lenses for the camera, then nullify the quality they provide with an inferior enlarging lens; however, a quality camera lens is not suitable for enlarging. Even a moderately good

Table 11-1.—Enlarging Lens Focal Lengths for Various Negative Sizes

Negative size	Lens focal length
35mm	50mm
120 (2 1/4 x 2 1/4) (6x6cm)	75mm
120 (2 1/4 x 2 3/4) (6x7cm)	105mm
4 x 5 inch	135-150mm

enlarging lens is better for enlarging than most camera lenses.

The focal length you use with an enlarger should be based on the size of the negative to be enlarged. (See table 11-1.) Generally speaking, the focal length of the enlarging lens for a given negative size should be the same as a normal-focal-length lens used by the camera for the negative.

While it is not necessary for the lens to cover the full area of the negative, the longer the lens focal length, the less magnification at a given lens-to-paper distance; therefore, you must have several lenses of various focal lengths available for your enlargers when you want to make large prints from small portions of your negatives.

Because an enlarger produces an image from a flat field (the negative) onto a flat field (the paper), depth of field is not a factor, except when distortion control (discussed later) is used. An enlarger lens can usually be used at large f/stops; however, when an enlarger lens is used at its maximum aperture, there may be some falloff of light at the edges of the circle of illumination. Therefore, an enlarger lens is usually stopped down one or two f/stops from wide open. Like a camera lens, when an enlarger lens is used at very small apertures, there is a loss of image definition due to diffraction.

ENLARGING PROCEDURE

The darkroom design, the equipment, and the arrangement for enlarging are basically the same as for contact printing. The safelights should be appropriate for the type of paper being printed. The size of the prints may require larger trays and greater amounts of solution, but they should be set up in the same way as for contact printing.

To produce good enlargements, you need good negatives, a clean enlarger, clean printing filters, correct exposure and development, and careful processing and finishing. Although most negatives can be printed by projection, there are a few desirable characteristics. A

good negative has normal density and contrast. It must be sharp and free from such defects as scratches, abrasions, dust, lint, and fingerprints.

ENLARGER AND EASEL ADJUSTMENTS

Insert the negative in the negative carrier so the emulsion side is down when placed in the enlarger. In other words, the base of the negative (the shiny side) should be up or facing the lamp when inserted into the enlarger. Clean the negative and be sure there is no dust on it. You can use the light from the enlarger to check for dust. Blow off any dust with a bulb syringe or low-pressure air. Then, use a camel-hair brush to brush or lift off any remaining dust. Replace the negative carrier containing the negative into the enlarger; ensure it is seated properly.

Set the paper guide or masking device on the easel to form the border width needed or use a preset easel. As an aid for composing and focusing the image accurately, place a sheet of white paper in the easel-the base side of the paper is used for a focusing sheet-then turn out all white lights.

Turn the enlarger lamp on, open the lens to its maximum aperture, and move the easel around until the desired portion of the image is in the picture area. Raise or lower the enlarger head on the upright standard or column and focus the image. Shift the easel as needed, and continue these adjustments until the image is enlarged (or reduced) to the desired size, focused sharply, and composed on the easel correctly.

The size of projection prints is limited by the optical system used and the working space available. A scene may be printed in sections on several sheets of paper and spliced together. Likewise, the enlarger can be turned 180 degrees and projected on the floor. If you use this baseboard method, be sure to counterweight the enlarger by placing a heavy weight on the baseboard to prevent the enlarger from tipping over.

The picture is easier to compose with the scene right-side up. When it is upside down from your point of view, the negative carrier should be rotated or removed and the negative repositioned. The image appears right-side up on the easel when it is positioned upside down in the negative carrier.

You should adjust the easel until the best composition is obtained. When composing the image, try to correct errors of image composition in the negative. The way the scene is composed on the negative may be a controlling factor in the final composition.

Straighten the horizon, and when possible, prevent it from cutting the print image in half. When the horizon is not to be included in the print, make sure vertical objects are parallel to the sides of the print. When the space around the point of interest of the picture is distracting, you can change the composition of the picture through cropping. You can do this by increasing or decreasing the magnification of the image and by readjusting the easel.

After the image is correctly composed and focused, the lens aperture should be stopped down so your basic exposure time is about 10 seconds. An exposure time of 10 seconds allows you to accomplish a normal amount of dodging and is fast enough to be practical for quantity production. The exact amount the lens should be stopped down depends on the density of the negative and the magnification of the image. This can be difficult to determine without experience. If you are new to printing, you should start by stopping down the lens to about $f/5.6$ or $f/8$ for a normal negative.

MAKING A TEST PRINT

There are many factors that affect exposure times in the enlarging process. Some of these factors are as follows:

- The light source and illumination system of the enlarger
 - ◆ The f /stop of the lens
 - ◆ The density of the negative
 - ◆ The degree of enlargement
 - ◆ The speed of the paper
- The density and color of the contrast printing filter

The best way for you to determine the correct enlarging exposure is by making a test strip. Although the test strip is the most reliable way to determine exposure, you do not need a test strip for every enlargement. It is, however, a wise practice whenever you are in doubt as to the exact exposure required.

A test strip for enlarging is made the same way as for contact printing. When making the enlargement test strip, you must try to select the proper printing filter based on negative contrast.

Once the printing filter has been determined, set the enlarger for producing the desired size prints. Set the lens f /stop at $f/5.6$ or $f/8$, for example. Next, examine

the projected image on the focusing paper in the easel and estimate the amount of exposure time you think the print requires. From experience, you estimate the correct exposure time to be about 15 seconds. Because your estimate may be incorrect, a logical procedure is to expose a test strip in four sections.

To make the actual test strip, you must do the following:

1. Place one test strip on the easel in a position to sample the highlights, midtones, and shadows.

2. Cover three quarters of the strip with opaque paper or cardboard and expose the uncovered section for 5 seconds.

3. Move the cardboard to cover one half of the strip and give another 5 seconds of exposure.

4. Again move the cardboard-this time to expose three quarters of the strip-and provide 5 seconds of exposure.

5. Now uncover the entire strip and expose it for another 5 seconds. This produces a strip with exposures of 5, 10, 15, and 20 seconds.

6. Process the test strip the same as contact prints.

7. Examine the processed test strip under white light and select the segment representing the exposure that gave the best results. If a time between two sections gives the best result, make another test at the estimated time. When you have selected the exposure, you are ready to make a full-size print-if the contrast is correct. If not, change filters and make another test strip.

The primary purpose for a test print is to determine the correct exposure, but it can also help you determine the correct contrast or printing filter to use. When the test print is too contrasty or too flat, make another test print with a higher or lower number of contrast printing filter.

When printing, contrast (the difference in tonal value between the highlights and shadows) is as important for you to determine as is the correct exposure. Almost all Navy imaging facilities use variable contrast printing papers. To control contrast with this type of paper, you must use variable contrast printing filters.

Unlike film, increasing the development time of paper does not increase the contrast significantly. In fact, when paper development is carried out much beyond the recommended time, contrast can actually decrease due to fogging. Likewise, short development times should not be used in an attempt to get lower contrast. The result

Table 11-2.-Multigrade Filter Selection Guide

Filter Number	Use
00	Normal prints from very contrasty negatives. Produces very flat prints from normal or low-contrast negatives.
2	Normal prints from normal negatives, flat prints from low-contrast negatives, and contrasty prints from contrasty negatives.
4	Normal prints from low-contrast negatives, and contrasty prints from normal or high-contrast negatives.
5	Normal prints from very low-contrast negatives, and very contrasty prints from normal negatives.

of short paper development times is usually a print that is not fully developed, and the print has poor tone quality and a “muddy” appearance.

Variable contrast printing filters are the only practical way of altering print contrast with variable contrast papers. Variable contrast papers have orthochromatic sensitivity. The blue light-sensitive part of the emulsion controls high contrast, and the green light-sensitive part controls low contrast. By using the proper variable contrast filter between the light source and the paper, you can control the contrast. Variable contrast filters range from yellow (low contrast) through deep magenta (high contrast).

When making test strips to determine correct exposure, you also need to determine the contrast. You do this by examining the shadow area of the test strip that has the correct highlight exposure. When the shadow area of this test is too light, the test does not have enough contrast. When the test does not have enough contrast, a higher number filter is required. When the shadow area is too dark, the test has too much contrast and a lower number filter is required.

Table 11-2 is based on using Ilford Multigrade filters and Ilford Multigrade papers. Ilford Multigrade filters are available in the following 12 grades: 00, 0,

PHC Carl Hinkle
302.308

Figure 11-10.—Comparison of a number 0, 2, and 5 contrast printing filter.

1/2, 1, 1 1/2, 2, 2 1/2, 3, 3 1/2, 4, 4 1/2, and 5. Use this table as a guide to help you determine the correct filter. The principles, also, apply to the use of filters not shown in the table, such as 0, 1, 1 1/2, 2 1/2, 3, 3 1/2, or 4 1/2.

Figure 11-10 shows the difference in contrast obtained from one negative using different contrast printing filters.

When using variable contrast paper and filters, you must remember the following:

- The filters should be clean and in good condition (not scratched, etc.). Like all filters, they fade and must be replaced.
- The density of filters changes with the different numbers. Filter numbers 0 - 3 1/2 require a one f/stop increase of exposure compared to the exposure when no filter is used. Filter numbers 4 - 5 require a one f/stop increase compared to the exposure when a 1 - 3 1/2 filter is used, or a two f/stop increase of exposure compared to the exposure when no filter is used. For example, when you make a test print with an exposure of f/8 at 10 seconds with a No. 3 contrast printing filter, and then make another test print with a No. 4 contrast printing filter, your new exposure will be f/5.6 at 10 seconds.
- It is possible to control local contrast by changing filters. For example, one possibility is for you to print an overall exposure with a No. 2 filter while holding

back or dodging the sky and then burning in the sky with a No. 1 filter. When printing with more than one filter, you should work from a full test print to determine the best approach.

- Study the manufacturer's directions so you can use their filter and paper combination to best advantage.

Many of us are guilty of throwing away the manufacturer's directions that come with photographic materials. By maintaining them in a reference book, you have a tremendous source of information available that can save time and materials.

Having determined the correct exposure and contrast, you are now ready to produce the production prints. Until you become proficient in printing, make test prints for each negative you print.

By adjusting the lens f/stop, you may use longer or shorter exposure times than the test exposure time determined previously, providing they do not become excessive in either direction. Very short exposures are not practical. Very long exposures subject the negative to excessive heat from the printing lamp and also waste time. Five seconds is the minimum amount of exposure time that you should use. Twenty seconds is about the longest exposure time required for normal negatives. A standard procedure is to change the exposure by varying the f/stop of the lens to bring the exposure time within practical limits.

Figure 11-11.—Grain focuser.

GRAIN FOCUSER

Focusing the negative image on the enlarging paper can be difficult when the negatives are dense or have no sharply defined lines that you can see in the projected image.

Focusing is easier and more consistent when you use a magnifier or grain focuser. A grain focuser magnifies the negative grain structure by 10X to 25X. This magnification allows you to focus the actual grain structure of the image. A grain focuser provides you with the sharpest focus you can get from a given negative.

The projected image of the negative is reflected by the mirror of the grain focuser to the eyepiece. The distance from the mirror to the eyepiece is equal to the distance from the mirror to the easel (fig. 11-11); therefore, when you see a sharp image of the grain structure in the magnifier, the image projected on the easel is equally sharp. The area of the negative visible in the magnifier is extremely small. You are not actually looking at details of the image but at the grain structure of the negative that actually produces the image.

To use the grain focuser, you should enlarge and compose the picture normally on an easel. Place the grain focuser on the easel with a sheet of focusing paper in it, so a central portion of the projected image reflects from the mirror into the eyepiece of the grain focuser. Examine the grain structure through the eyepiece and adjust the fine focus until the grain structure is in absolutely sharp focus.

CREATIVE CONTROLS IN PRINTING

Because of the many ways you can control the final appearance of the photograph, enlarging is a creative procedure. You can use printing exposure to make your prints lighter or darker, and the contrast can be altered by your choice of printing filters. You, also, have other creative controls available, such as cropping (composition), dodging, printing, or burning in, vignetting, diffusing, correcting image distortion, and so on.

You should devote as much attention and care to printing as to making the original negative; otherwise, you do an injustice to your skill and reputation as a photographer.

COMPOSITION AND CROPPING

Printing only a part of the entire image recorded on a negative is called “cropping.” Cropping is the procedure in printing used to improve the composition of the photograph. Most photographs are intended to present an idea or provide the viewer with some type of information. The better the composition of the finished picture, the better it communicates the intended message.

Photographic composition should be controlled or established with the camera when the picture is taken; however, the majority of photographs can be improved during the printing process by cropping. You can use cropping to eliminate distracting or unwanted scene elements, to straighten a tilted horizon, to alter the center of interest, or to strengthen leading lines.

Since personal opinions differ, there are no hard-and-fast rules for cropping; however, the following are rules of thumb that may help you produce pictures that are pleasing to most people:

- Crop out any elements at the edges of the picture area that may draw attention from the intended center of interest.
- The center of interest should not normally be located in the physical center of the print. The center of interest should be somewhat to the left or right and a little below or above the physical center of the picture. The exact location for the center of interest depends on the subject and the format of the print.
- Horizontal, vertical, and diagonal lines should not divide the photograph into equal parts. The horizon in a photograph should be absolutely horizontal. The vertical lines of buildings, with one exception, should

303.57

Figure 11-12.—Cropping arms can be used to determine cropping.

be vertical. The one exception is the vertical lines of buildings that naturally appear to converge. In this case, the central vertical line, either real or imaginary, should be rendered as vertical.

- People or animals shown in profile or near profile within a photograph should appear to be looking into the picture, not out of it; for example, the subject should have more picture area in front than behind.

- Unless you are producing micro- or macro-photography, the printed images should not normally be larger than the actual size of the subject.

- The image area of a picture should appear to have a solid support. This effect can sometimes be achieved by printing the lower part of the picture darker than the upper part

- In a landscape or seascape picture, print the foreground somewhat darker than the middle distance, and print the middle distance darker than the far distance. Then gradually increase the density of the sky from the horizon upward. This creates a feeling or illusion of depth.

A contact print (proof print) of the full negative to be printed is helpful in determining the most effective cropping for the picture.

Have available a set of cropping arms such as the ones shown in figure 11-12. Cropping arms can be cut from pieces of cardboard. Be sure the arms have true right angles. You should use the following procedure to crop or mark the proof print:

303.58

Figure 11-13.—Marking the print to be cropped.

1. Place the cropping arms over the proof print and move them about until you have the desired cropping, composition, and picture proportion or format.

2. With the cropping arms held in place on the proof, mark the print with a grease pencil (or other suitable marker) to outline the desired area or composition of the picture (fig. 11-13). You should use the marked proof print as a guide for setting up the enlarger and easel.

3. With the negative in the enlarger and the printing lamp turned on, adjust the enlarger for the desired image size and cropping. Use the proof print as a visual guide.

4. Adjust the adjustable masks on the easel to the correct format and desired cropping. The adjustable masking device on the easel should be adjusted so at least a 1/4-inch white border is left on all four sides of the finished print. Excess border can be cut off the print after it is processed.

There may be occasions when you may want to produce prints with borders larger than 1/4 inch or with borders of various widths, such as 1/2 inch at the top and sides and 1 1/2 inches at the bottom, or you may want prints without borders or with black borders. To make a print without borders, cut the borders off after the print is processed or use a borderless type of easel.

5. Adjust the picture composition by moving the easel, by changing the border masks, or by changing the picture enlargement or any combination of these until

the projected image is the same as the cropped area in the proof print.

LOCAL PRINT CONTROL

No matter how good your camera work, somewhere in the negative there will probably be areas that do not print correctly. A “straight” enlargement from a negative is seldom the best possible print. When everything has been done to match the negative with the proper printing filter and still the print is unsatisfactory, you may resort to manipulating the light while exposing the paper. This manipulation may be dodging to prevent part of the image from getting too dark or it may be burning-in to produce detail from a part of the negative that is too dense. Local print control can be used to compensate for uneven lighting of the scene photographed or to provide more prominence to a selected part of the picture.

Dodging

As discussed before in contact printing, you may often find it necessary to dodge or hold back some parts of images to produce the best print. When projection printing, hold the dodging material in the beam of light, so its location and coverage can be seen and controlled during the printing exposure. The dodging tool is placed between the lens and the printing paper so it prevents light from falling on the area being dodged. The shadow area the dodging tool creates may be small or large. The coverage depends on the size of the tool and the distance from the printing paper where the dodging tool is held. Dodging is generally necessary for only part of the total exposure time. The tool being used must be moved constantly to prevent a sharp line between the area being dodged and other parts of the image.

Accurate dodging may be done with your hands or various shaped tools. Your hands, when used as dodging tools, can cast a variety of different sizes and shapes of shadows to hold back unwanted light from the print. Some photographers prefer to use dodging tools, such as a stiff wire with various sizes and shapes of black cardboard or crumpled cellophane attached (fig. 11-14). Another dodging tool is a loop of a thin, stiff wire bent to the desired size and shape. The loop is then covered with black masking tape. Even a plain piece of cardboard can make an effective dodging tool.

Because light is held back from an area during dodging, the dodged area receives less exposure than the surrounding image area. Thus the dodged area of the

Figure 11-14.—Dodging tool.

processed print is lighter than it would have been had dodging not been used.

Dodging can be used for creative and corrective effects. It is used to hold back shadow areas, thereby preventing these areas from printing too dark and losing detail; for example, part of a person’s face may be too much in shadow because of the hat he or she is wearing, while the rest of the face is brightly lighted. You can dodge or hold back some of the light from the shadow area of the face image; this keeps the shadow from printing dark, and a more pleasing and detailed photograph is produced.

The amount of time you should dodge can vary widely, depending on the subject, the negative, and the overall exposure time. Even an experienced printer may have to produce several test prints to determine the correct amount of dodging.

Remember, to prevent any distinct outline of the dodging tool from reproducing in the print, you must keep the dodging tool in constant motion during the exposure. Use a circular, sideways, or shaking movements to accomplish this.

Burning-in

Burning-in makes an area within a print darker than it would be otherwise. A burning-in tool is usually a piece of cardboard with a hole in the center that is

PH1 Anthony Contos
303.63.2

Figure 11-15.—Vignetted head-and-shoulders portrait.

smaller but approximately the same shape as the area to be burned in. Your hands can be shaped to form a hole to allow light to pass.

A burning-in tool is positioned between the enlarger lens and the printing paper, so light passes through the hole and exposes only that part of the paper you want to

print darker. The rest of the image is blocked by either the tool or your hand.

For burning in, the usual procedure is to give the printing paper the overall required exposure during which time any required dodging is performed. Then re-expose the area to be darkened.

PHC Carl Hinkle
302.309

Figure 11-16.—Head-and-shoulders portrait using diffusing techniques.

Some areas of a negative that may require burning in are the dense areas that would otherwise reproduce as pure white with little or no detail or very light gray in the print; for example, a bright sky, a white uniform, a white cake, or highlights on a face.

Like dodging, to prevent an outline of the tool from reproducing, you should keep the tool in constant motion during the burning-in exposure.

Vignetting

In printing, vignetting is a technique that causes the image to fade gradually into the background toward the corners of the print. A vignette effect is produced by projecting the desired negative image area through a large hole cut in a piece of cardboard or by dodging the central image area during part of the exposure time. When the background is to be printed light, the entire exposure should be made through the vignetting card. When the edges of the hole are serrated, the outline of the vignette will be soft and diffused. In most cases, a soft, diffused vignette produces the most pleasing result.

Head-and-shoulders portraits are usually the most suitable for vignetting, although vignetting may be applied to other subjects (fig. 11-15). A photograph with a light background provides the most pleasing vignette results. For a head-and-shoulders portrait, the vignetting

card should have an egg-shaped hole cut in it. The subject in a vignette should be a little smaller than it is in a straight nonvignetted print. Leave plenty of space around the image. Balance the head-and-shoulders image on the paper by leaving more blank paper below the image than above it. The blank paper at the sides should be about equal, but less than at the top. As with dodging and burning in, the vignetting card must be kept moving during the exposure.

Diffusing

Photographs can be diffused so sharp lines of the image are softened, subdued, or blurred slightly in the reproduction. Diffusion can be used to produce a hazy effect, such as the effect seen on a warm lake in early morning. In printing portrait negatives, diffusion can be used to subdue the reproduction of facial blemishes or wrinkles. The effects of harsh portrait lighting or retouching also may be softened with diffusion (fig. 11-16).

The best diffused enlargements are made using a glass diffusing disk placed under the lens of the enlarger. Other suitable diffusing materials are transparent cellophane, either smooth or wrinkled, or a piece of panty hose, or similar fabric. Dark gray or black is preferable.

The amount of diffusing with a given material is controlled by the distance of the material from the lens of the enlarger and the density of the diffusing material. Diffusing tends to lower image contrast; therefore, you may need to use a higher contrast printing filter than normally required for a given negative. The exposure through the diffusing material should be about one third of the total required exposure time.

To use dodging, burning-in, vignetting, and diffusing effectively, you should make one full-straight (uncorrected) print, using the basic exposure determined with your test strips. Study this print and determine the location(s) you are going to dodge, burn in, and so forth. The application of these techniques may appear time-consuming, but you will make professional-quality prints that are rich in detail and mood.

MINIMIZING GRAININESS

As you know, most black-and-white photographic images on film emulsions are made of fine grains of silver. Because of this silver grain structure, enlargements, especially large ones, may appear “grainy.” The graininess of a print is a direct result of the graininess of the negative and the degree of enlargement. The graininess of a print, however, may be modified to a limited extent during the printing stage by the following techniques:

- The diffusion enlarger should be used where negative graininess is serious and objectionable in the print.
- The appearance of graininess in the print can be reduced by using a rough, surface paper instead of a smooth, glossy paper.
- A diffuser used between the enlarger lens and the printing paper helps subdue the appearance of grain. Crumpled cellophane, fine mesh screen, or a piece of nylon stocking can be used as a diffuser.
- The enlarger can be set to project an image that is slightly out of focus.

The permissible graininess in a print depends very much on the viewing conditions. For a large display print to be viewed from a relatively great distance, more graininess can be tolerated as compared to a smaller print held in a person's hand for viewing.

Figure 11-17.—Distortion corrected by tilting the easel.

DISTORTION CONTROL

When you tilt the camera upward to make a picture of a tall building, the vertical lines converge and the building walls seem to be at the point of collapsing. A view camera is equipped with movements that allow the film to be parallel, or nearly so, with the subject, in spite of the viewpoint; however, most of the negatives you print probably are not made with a view camera. Many negatives show an undesirable, noticeable convergence of lines. Changes in these images can be made by tilting the head on some enlargers or by tilting the easel and paper to correct image distortion (fig. 11-17).

Most enlargers have an easel separate from the enlarger. Because the easel is separate, it can be tilted by blocking it up on one end. A small diaphragm opening (high f/stop) must be used to increase the depth of focus to include both the part of the easel nearest the lens and the part of the easel farthest from the lens. Within the limits of what you can keep in focus, you can correct some or all of the distortion. With some enlargers, you can tilt the negative carrier by propping up one side with one or more coins.

One big disadvantage of tilting the easel is that an extremely small diaphragm opening must be used for depth of sharp focus. The use of a small diaphragm opening makes focusing and composition difficult. This makes it necessary to use long exposure times.

PROCESSING DEFECTS

The prints you produce will not be perfect every time. Table 11-3 shows some of the most common defects found in black-and-white prints. Use this table to identify and correct print defects.

Table 11-1-Print Defects

Defect	Appearance	Cause	Prevention
Abrasion marks or streaks.	Surface of paper abraded or scratched; results in fine dark lines on the surface of the print, especially with glossy paper.	Friction or rubbing on the surface of the paper.	Store paper boxes on their edges; handle carefully; make sure that processing solutions are free from grit or undissolved particles. Inspect and clean rollers of processing machine.
Bad definition in parts of print.	Parts of print poorly defined, blurred, as if out of focus, though negative is sharp.	Buckling of paper in the contact printer, thereby blurring these parts.	Check contact pad in printer. Pressure springs should be firm and strong.
Bad definition over entire print.	Completely blurred print from sharp negative.	In contact prints, because of printing from the wrong side of the negative. In enlargements, careless focusing or, more often, vibration of the enlarger, especially at high magnification.	In contact printing, the paper emulsion must always be in contact with the emulsion of the negative. Enlargers should be braced firmly and protected from vibration
Round white (light) spots on print.	Round white or light spots in picture area.	Air bells prevent developer from working on parts of paper.	Proper agitation of print in developer.
Round dark spots on prints.	Round or circular-shaped dark spots.	Air bells on surface of print in fixing bath allows developer to continue to work	Use a stop bath between developer and fixer. Agitate thoroughly in fixing bath.
Round discolored spots appearing some time after drying.	Round discolored spots in picture area of print.	Air bells in washing prevent removal of hypo in these areas	Thorough washing with constant agitation.
Small, well-defined brown spots.	Brown spots on front or back of print.	Particles of rust in wash water from rusty wash tanks or water pipes and/or particles of chemical dust.	Where quantities of rust are present, use a water filter in the line.

Table 11-3.–Print Defects–Continued

Defect	Appearance	Cause	Prevention
Tone of image unsatisfactory.	Greenish or muddy tone.	Overexposed then underdeveloped	Correctly exposed and developed.
Excessive contrast.	Contrasty print.	Wrong printing filter used.	Use a lower number filter.
Lacks contrast.	Flat print.	Wrong printing filter used.	Use a higher number filter
Fading	Fading or tarnishing.	Incomplecte fixing and/or washing.	Give adequate fixation and washing

CHAPTER 12

COLOR PRINTING

The mechanics of color printing are similar to black-and-white printing. Once you have mastered the techniques of black-and-white printing, you will have a solid foundation to build your knowledge and skills in color printing. The most difficult task in color printing is distinguishing between various and sometimes subtle colors and selecting filters to produce a color balanced print. That is not as difficult as it may sound. Through time and practice, you will make excellent color prints; however, before color printing is discussed, the principles of color photography and how they apply to color printing will be reviewed.

PRINCIPLES OF COLOR PHOTOGRAPHY

Most people see in color and expect their photographs to be in color. Because of customer demands and the cost benefits involved, color photography has nearly replaced black-and-white photography in Navy imaging facilities. Few amateur photographers understand the complexity of color reproduction in color photography. Most of these amateurs take their unprocessed film to a drug store or a 1-hour photo finisher. As a Navy Photographer's Mate, you are a professional. To produce professional quality color photographs, you must have a basic understanding of the color process.

COLOR IS LIGHT

The color you see is simply light. Where there is no light, there is no color. When you "see" a colored object, what you are actually seeing is the light reflected or emitted from that object; therefore, the light alone is what you see and not the actual object.

The color of light people are most familiar with is white. Actually, white light is made up of all the colors, although they are impossible to see directly. When you see white light reflected from a sheet of white paper, you are actually seeing an equal mixture of red, green, and blue light being reflected in equal amounts. You must realize and understand this fact before you print color.

Usually white is thought of as no color; however, it is more accurate to think of it as all colors. When one of the colors is absent, the color is not white light, but a different color-green, for example. When magenta (a bluish red color) is absent, the resulting color is green. When cyan (a greenish blue color) is absent, the color is red, and so forth.

As you read this chapter and when you color print, you may find it helpful to think of a color as white with something missing; that is,

- blue is minus yellow;
- ◆ green is minus magenta;
- ◆ red is minus cyan;
- ◆ yellow is minus blue;
- ◆ magenta is minus green; and
- ◆ cyan is minus red.

Also keep in mind that

- ◆ all color is light; and
- ◆ white is all colors.

LIGHT PRIMARIES

White light is a mixture of all the colors of light; however, only three primary colors are actually needed to make white light. These three primary colors are red, green, and blue. Not only do these three light primaries produce white light, but they produce any and all other colors; for example, imagine a blue, a green, and a red spotlight shining on a white screen so the spotlight circles partly overlap. There are three places where two of the light primaries overlap and one place where all three light primaries overlap. In the areas where two primaries overlap, a distinctly new color is created

C303.73

Figure 12-1.—Mixed beams of the three primary colors of light.

(fig. 12-1). When you overlap red and green, yellow is created; green and blue, cyan is created; blue and red, magenta is created. In the area where all three light primaries overlap, you, of course, have white.

In the actual production of color prints, you should remember that

- yellow is greenish red;
- cyan is greenish blue; and
- ◆ magenta is bluish red.

The above information should help you remember the colors of light that make up yellow, cyan, and magenta, which are the light secondaries. Light secondaries are the colors produced when two light primaries are mixed.

Additive Primaries

Now that you have an understanding of light primaries, they will be called the additive primaries. The name *additive primaries* indicates that certain colors of light can be added together to create distinctly new colors.

As explained in chapter 2, color films and papers have three separate emulsion layers that are sensitive to red, green, and blue light. Because the emulsions are sensitive to the additive primaries, they can record all colors. In the three emulsion layers, three separate, superimposed images are formed and when viewed together, they give a full range of colors.

The color formation, however, is not direct; for example, in a color print, a cyan image is formed in the top or red sensitive emulsion layer, a magenta image in the middle or green sensitive layer, and a yellow image in the bottom or blue sensitive layer. These three colors or dyes—cyan, magenta, and yellow—are what produce the colors we see when we view a color print. These colors—cyan, magenta, and yellow—are called the **subtractive primaries**.

Subtractive Primaries

Keep in mind that the **additive primaries**—red, green, and blue—are the basic starting colors from which all other colors of light can be created. When you are working with light, the additive primaries produce all the other colors; however, they will not do this as dyes or pigments; for example, blue and green dyes cannot be mixed to produce cyan, though blue and green light can.

For dyes and pigments, another set of primaries are needed. This other set of primaries happens to be yellow, cyan, and magenta. Dye couplers are what form the colors within a color print (or film). The dye primaries—cyan, magenta, and yellow—can be used separately or superimposed (mixed), one image over the other, to produce other colors; that is,

- ◆ cyan + magenta = blue;
- ◆ magenta + yellow = red; and
- ◆ yellow + cyan = green.

The colorant primaries—cyan, magenta, and yellow—are called the subtractive primaries because they subtract certain colors from the light falling on them.

Anything that is colored is subtracting something from white light; that is, an object appears a certain color because it is subtracting or absorbing a certain other color or colors from the light falling upon it; for example, an object that appears

- red subtracts green and blue (cyan) light;
- ◆ green subtracts red and blue (magenta) light;
- blue subtracts green and red (yellow) light;
- ◆ magenta subtracts green light;
- cyan subtracts red light; and
- yellow subtracts blue light.

Figure 12-2.—Color star.

C303.74

This whole concept of color by subtraction may seem confusing at first, but if you accept this concept, it will suddenly become very clear. Color printing is built around color by subtraction.

COLOR STAR

To help understand color theory, draw a color star and use it through the color process (fig. 12-2). With a color star, both additive and subtractive color effects can be illustrated.

The color star shows how colors can be mixed. Any two primaries (colors) on opposing points of a given triangle, when mixed, will produce the color between them; for example,

- green and red = yellow;
- yellow and cyan = green; and
- green and blue = cyan.

Just as important, the color star shows the colors that will neutralize each other. These colors are called complementary colors and are located across from each other; that is

- yellow is complementary to blue;
- magenta is complementary to green; and
- cyan is complementary to red.

Thus yellow neutralizes blue, blue neutralizes yellow, red neutralizes cyan, cyan neutralizes red, and so forth.

When colors are neutralized, the results are grays or blacks. That is called neutral density. The neutral density may be either full or partial, depending on the relative strengths and amounts of the neutralizing colors; for example, equal amounts of blue and yellow produce neutral density. A weak blue and a strong yellow yields a grayish yellow.

The information on the color star can be applied directly to color printing and color filtration. The filters used in color printing subtract colors from the light source of the enlarger before it reaches the color printing paper; for example, to subtract green from the light, you use a magenta filter, or to subtract blue, you use a yellow filter or vice versa.

In color printing, filters are always used to subtract a particular color. You can determine which filter subtracts a given color from the light source of the enlarger by finding its opposite or complementary color on the color star. For example, you want to subtract green from the light. First, find green on the color star. Next, locate the complementary color of green by looking across from it. You have located the color, magenta; therefore, to remove green from the light source, you must add magenta filtration in the enlarger.

The basic overview of the principles of color photography applies directly to color printing. If you need additional review of light and color principles, refer to chapter 1 of this training manual. The remainder of this chapter should help you get a better understanding of color printing and provide the information you need to make good, professional quality color prints.

COLOR ENLARGERS AND PRINTERS

Other than the basic exposure factors of intensity and time, there are other factors to consider in printing equipment. Some of these considerations are as follows:

- Quality of the lens
- Color temperature of the light source used for printing
- Corrective filters
- Accuracy of the enlarger timer
- Stability of the power (voltage) supply

- Ease of operation in total darkness

A good quality enlarger is required to produce high-quality color prints. Color enlargers used in Navy imaging facilities are diffusion type of enlargers. Like all image-forming equipment, the lens is an integral part of the enlarging system. The lens used in a color enlarger must be free of chromatic aberration; that is, it must be a color-corrected lens.

COLOR TEMPERATURE

The color temperature of light used to expose the color material must match the spectral sensitivity of the color material. This is true when making the original camera exposure, and it is also true when you are printing color materials. In color printing equipment, color temperature is usually regulated by adding filters to balance the light source and by regulating the voltage source supplying the lamp.

Corrective Filters

In color printing, three emulsion layers in the printing material must be correctly exposed from the three color images in the negative. The exposure of these three layers is manipulated by both exposure time and the color quality of the exposing light reaching the paper. The color or quality of light is altered by placing color filters in the light beam of the enlarger. You can use color printing (CP), color compensating (CC), or dichroic filters. CP and dichroic filters are placed between the light source and the negative. Generally, dichroic filters have replaced CP filters. Dichroic filters more accurately control the light, and unlike gelatin filters, do not fade over time. CC filters are placed between the lens and the light-sensitive paper.

The filters that control the exposing light are called the filter pack. The basic filter pack differs among each characteristic of color negative film; that is, film size, manufacturer, film type, and film speed. For example, the basic filter pack for 35mm Kodak Vericolor III differs from the basic filter pack of 120 Kodak Vericolor III. The basic filter pack for 35mm Scotchcolor differs from the basic filter pack of 35mm Fuji color. The basic filter pack for Kodacolor Gold differs from Kodak Vericolor III. The basic filter pack for Kodacolor 100 differs from the basic filter pack of Kodacolor 400.

In addition to CP, CC, and dichroic filters, a CP2B or equivalent filter is usually built into the enlarger to absorb ultraviolet radiation emitted by the light source.

Voltage Regulation

Fluctuations in line voltage are more common than most people realize. Power fluctuations affect both the intensity and color quality of a light source. As little as a 5-volt variation in the normal operating range (100-125volts) can change the output of a lamp by about 15 percent. This change in voltage results in a change in the color quality of the light source. This variation is about the equivalent of a CC10 filter.

To prevent voltage fluctuations, you must connect the enlarger to a voltage regulator. Most voltage regulators provide a constant voltage between 95 to 120 volts.

Two main types of color enlargers are in common use by the Navy. The two color enlargers differ in the way they control the exposing light. They are the subtractive and additive printers.

SUBTRACTIVE PRINTERS

The subtractive type of color enlarger uses a dial-in dichroic filtration system. This type of color enlarger has three filtration controls that move yellow, cyan, and magenta filters into the path of the exposing light. Segments of the dichroic filters are moved in and out of the exposing light beam on calibrated cams. This type of filtration system provides accurate and repeatable filter pack combinations.

Most color enlargers use a tungsten-halogen light source. These light sources produce a great amount of heat. When a tungsten-halogen light source is used, the color printer must have forced-air cooling fans in addition to the heat-absorbing glass. An ultraviolet absorber, such as a Kodak Wratten Filter No. 2B (CP2B), must always be included in the light beam, preferably above the negative. The most common type of subtractive printer used in the Navy is the Chromega D dichroic enlarger.

NOTE: Never touch a tungsten-halogen bulb. Handle it only by the edges or reflector cone. Oil from your fingers can heat up and create a hot spot on the light bulb, causing it to burn out. If you touch the bulb, clean it with a soft cloth and isopropyl alcohol. Allow the bulb to dry thoroughly before energizing.

ADDITIVE PRINTERS

The additive type of color enlarger uses the additive or primary colors of light (red, green, and blue) to expose color printing paper. This type of enlarger uses

PH2 Myer III
302.260

Figure 12-3.—Bessler Model 45A color enlarger.

filters either above the negative (CP filters) or below the lens (CC filters) to control the color quality of the exposing light.

Bessler color enlargers (fig. 12-3) are used in many Navy imaging facilities. The Bessler Model 45A uses pulsed-xenon tubes to expose the color printing paper. The xenon tubes are mounted at the top of the head of the enlarger above red, green, and blue filters. The amount of red, green, and blue light is controlled by the number of flashes through each color filter. By adjusting the number or length of time that the filtered-light sources flash, you can correct the color balance of the print. The color head of the enlarger is normally programmed to a color analyzer that is used to provide acceptable color prints.

PRINTING COLOR NEGATIVES

For many years color printing was difficult to achieve; however, through technical advances in

light-sensitive materials, chemicals, and printing equipment, color printing is as flexible and practical as black-and-white printing. The primary interest to you, as a Navy Photographer's Mate, is to produce color prints with an acceptable color reproduction of the original scene.

Good color prints are not difficult to make. Anyone who has normal color vision and can apply the principles of color theory can quickly learn to make good color prints.

NEGATIVE TO POSITIVE PROCESS

Like all negative materials, the images recorded on color negative films are completely reversed from the original scene as follows:

- Darker hues are recorded as lighter hues;
- Red is recorded as cyan;
- Green is recorded as magenta; and
- Blue is recorded as yellow.

To record the image as it appeared in the original scene, you must print the color negative onto a second tripack material—the color printing paper. If you need to refresh your memory on the characteristics of color printing paper, refer to chapter 2.

The theory of color printing is simple when you think through the stages of color reproduction. Since the colors reproduced in the color negative are complementary to the original subject colors, a red car is cyan in the negative. Cyan is a combination of blue and green; therefore, the two emulsion layers in the paper that are sensitive to blue and green are affected when the negative is printed. Then during print processing, yellow dye forms in the exposed portion of the blue sensitive layer of the paper, and magenta dye forms in the exposed portion of the green sensitive layer of the paper. Yellow and magenta in combination produce red; therefore, the red car is reproduced in its original color. All the other colors form in the same way.

CUSTOM COLOR PRINTING

In black-and-white printing, the controlling variables are primarily density and contrast. In color printing, the variables include density and the color of individual objects in the scene as well as the overall color balance of the print. The mood of a color print can be changed by altering the color balance. A winter landscape may be printed on the blue side to intensify

the feeling of coldness. Portraits, on the other hand, are usually warm with glowing flesh tones, reflecting health and happiness. Because of tightly controlled and standardized processing of color negatives, contrast is not a major variable in color printing. There are several color papers manufactured that provide higher than normal contrast. Generally, these high contrast papers are used for illustrative purposes and not normal pictorial photography. Consult the *Photo-Lab-Index* for more information on color papers.

It is unlikely that you will produce an acceptable color print on your first attempt. When you are considering the density and color balance of a test print, think in terms of the three dye layers and their individual exposures. When the paper is exposed through the color negative, the cyan, magenta, and yellow dye images control the amounts of red, green, and blue light that reach the emulsion layers of the paper. Increasing the exposure of the emulsion layers of the paper increases the dye density of that layer and vice versa.

It is helpful to think how the color quality of light affects the paper. Remember that the color negative and the color paper produce negative images. The more red light the paper receives, the more cyan dye produced. The more green light the paper receives, the more magenta dye is produced in the green sensitive layer. The more blue light the paper receives, the more yellow dyes created in the paper.

Color paper is balanced in manufacturing so a combination of magenta and yellow filters in the printer light source color balances a print from properly exposed negatives. Because of the variations in the color temperature of light sources (both picture taking and printer), processing, and light-sensitive emulsions, the required combination of filters can change from negative to negative. You must evaluate the test print in terms of density and color balance and determine which filter combination and exposure time accurately represents the original scene.

MAKING COLOR PRINTS

The procedures for setting up the enlarger and composing and cropping the image in color printing are basically the same as black-and-white printing. The major difference is that custom color printing on an enlarger must be carried out in complete darkness.

THE COLOR NEGATIVE

When making your first test print, you should use a negative that is properly exposed; it should also contain

some neutral areas (ideally, a gray card). The subject matter of the negative should be typical of the printing job or of those negatives that will be printed in the future.

The negative must be free from dust and placed in the enlarger, with the emulsion side down toward the lens (base side up). The base side is facing you when you can read the manufacturer's lettering on the edges of the film. You must be sure that no stray light escapes from around the edges of the negative. Masks of black paper or black masking tape in the negative carrier prevent stray light from fogging the paper.

ENLARGER SETUP

Setting up the enlarger and cropping the image on the easel is basically the same in color printing as in black and white; however, when possible, remove the filter pack and compose and focus under white light. By removing the filter pack, you can project a brighter image on the easel, making composing and focusing easier.

Since enlarging equipment varies considerably, it is difficult to specify exact exposure times and filtration for a properly exposed print. You should start with a basic filter pack that has already been established in your imaging facility, or consult the data sheet packaged with the color printing paper or use the *Photo-Lab-Index* as a reference to arrive at a starting exposure time and filter pack

JUDGING TEST PRINTS

When making color prints, you must always obtain the proper print density before you evaluate the color balance. Several ways are used to judge test prints. Before test prints are viewed, however, there are some lighting factors to be considered.

Viewing Conditions

The color quality of the viewing light source strongly influences the apparent color balance of the print. Ideally, the light in the evaluation area should be the same color quality and intensity as the light under which the final print is to be viewed. From a practical standpoint, some average conditions are used.

Several factors are important in specifying light sources for viewing color prints. These are intensity, color temperature, and color rendering index. The intensity of the light source influences the amount of detail that can be seen in a print. For good viewing, a light source should provide an illuminance of 1400 lux

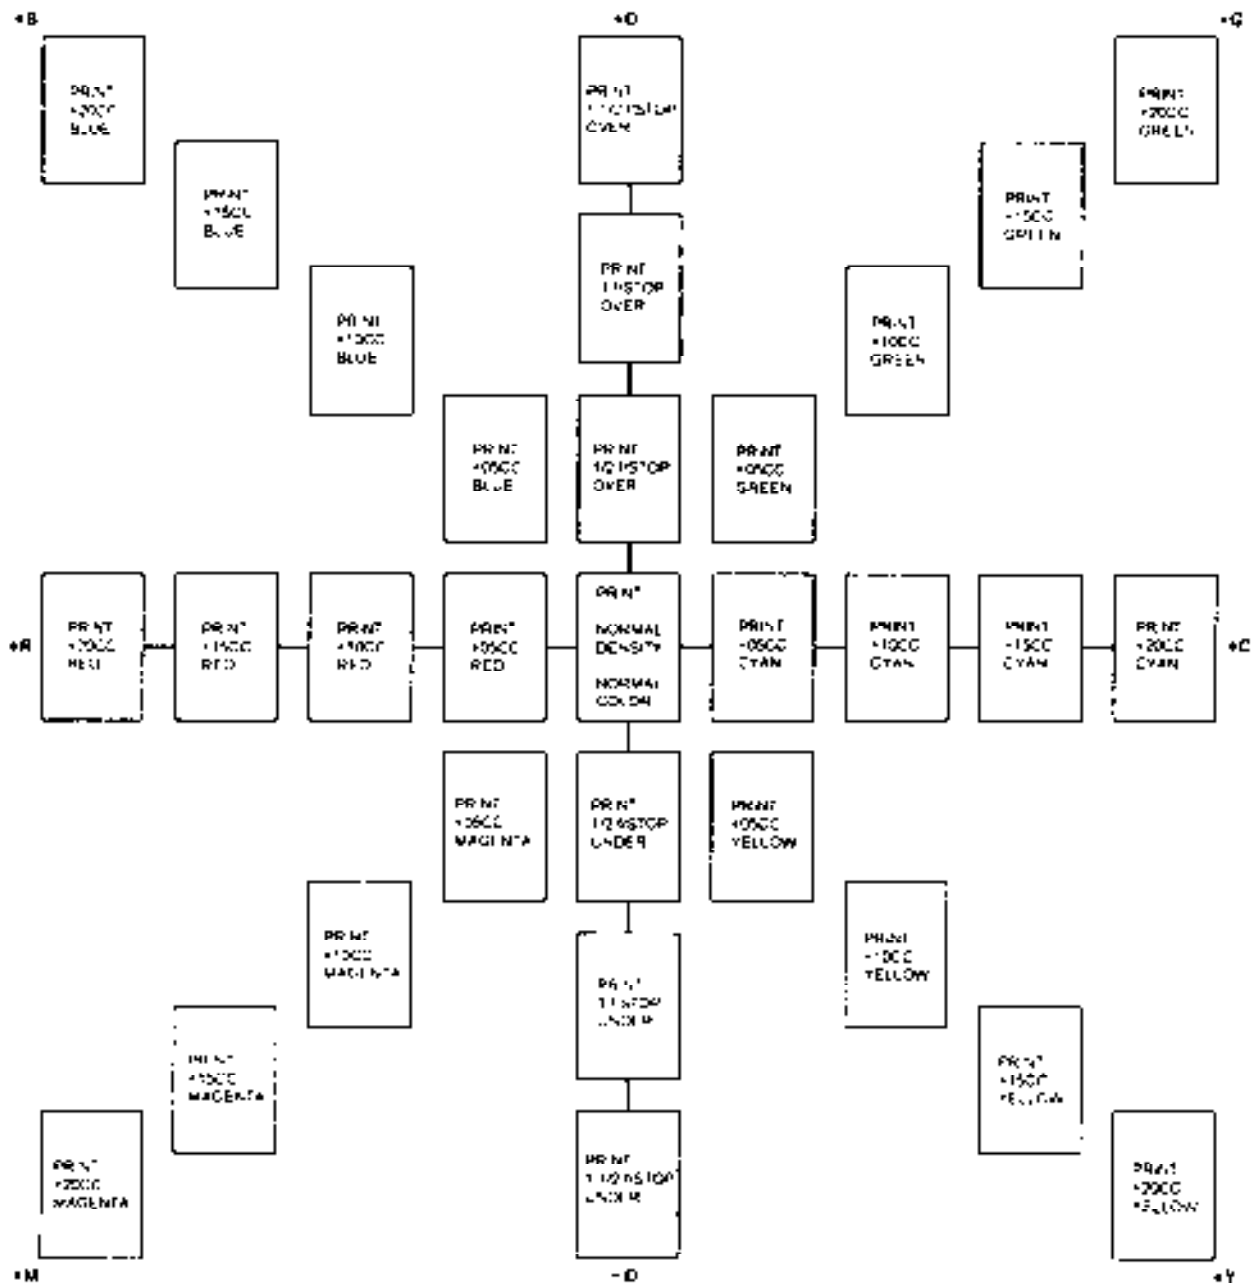

Figure 12-4.—Ring around.

± 590 lux (130 footcandles ± 55 footcandles). The color temperature of the light source should be between 3800 K and 5000 K. The most important characteristic of the light source is the color rendering index (CRI). The CRI is a scale from 0 to 100 and is used to describe the visual effect of a light source on eight standard pastel colors. For good color rendering in the prints being viewed, the CRI of the light source should be between 85 and 100.

Fluorescent tubes, such as the Westinghouse Living White or the Deluxe Cool White tubes (made by several manufacturers), have at least a CRI of 85 and a color

temperature near 4000 K. Satisfactory results also can be obtained by using a mixture of incandescent and fluorescent light. For each pair of 40-watt Deluxe Cool White fluorescent tubes, a 75-watt frosted tungsten bulb should be used.

Ring Around

Comparing the test print to a series of prints that vary from a standard print (correct density and color balance) in known amounts is a simple method of determining color and density correction (fig. 12-4). Comparing your test print to a ring around is particularly

helpful when your test print is far from being correct. When using a ring around, you should match the test print as closely as possible to one of the prints. The amount and color of filtration you should add or subtract from the filter pack are the same as indicated on the ring around.

When the test print is reasonably close to being correct, you can predict the final exposure conditions accurately. Once again, remember how exposure affects the three dye layers of the paper. That will simplify the choice of selecting the correct filtration.

Color Printing Viewing Filters

When a test print is reasonably close to the desired color balance, viewing it through color printing viewing filters helps to determine what color change is needed. Color printing viewing filters come in six filter colors: red, green, blue, cyan, magenta, and yellow. Each color is represented in 10, 20, and 40 density values.

To use a filter, hold it several feet away from the print and light source. Quickly flick the filter in and out of your line of vision to see the color correction the filter makes. Since these filters tend to overcorrect the highlights and undercorrect the shadows, you should view the lighter middle tones through the filters to determine the desired color balance. Try several filters of different values and colors when evaluating a test print; for example, when the print looks “cold” to you, evaluate it through a series of red, magenta, and yellow filters to determine whether the color in excess is cyan, green, or blue. Similarly, viewing a “warm” print through cyan, green, and blue filters will determine whether the color in excess is red, magenta, or yellow.

Since the contrast of print materials is fairly high, a filter used in exposing a print tends to produce a greater change in color balance than the visual effect of viewing a print through a filter. In general, the filtration change to the filter pack should be one half of the viewing filter that makes the lighter middle tones of the test print appear correct; for example, you have determined that when viewing a test print through a 20CC green filter, the color balance looks correct; therefore, you would make a 10CC change to your filter pack

Suppose, again, that the test print is too blue; that is, not enough yellow dye was produced. The print will look best through a 10CC yellow filter. Since blue light creates yellow dyes, we must increase the amount of blue light reaching the paper by 05CC. You should do this by subtracting 05CC of yellow filtration (for subtractive printing) or subtracting 05CC of blue

filtration (for additive printing). When a 20M filter is best for viewing, subtract 10CC G (additive printer) or 10M (subtractive printer) from the pack to produce the desired correction.

MODIFYING THE FILTER PACK

Remember, you must produce a test print with proper density before you change the filtration on your enlarger or printer. Before modifying the filter pack in the enlarger or printer, you must keep in mind what type of printer you are using. Modifying the filter pack for a subtractive type printer is completely opposite from the filter pack adjustment necessary on an additive printer.

Subtractive Printers or Enlargers

When you have determined what color dominates the test print, that filter or its complement must be added or subtracted from the filter pack. Whenever possible, you should subtract filtration.

Table 12-1 may be useful in determining what filter adjustment should be made.

The following rough guide may also be helpful: When a slight shift in color balance is needed, use an 05 or 10 filter change; when a moderate shift is needed, use a 15 or 20 filter change; and when the shift required is too large to estimate, try a 30 filter change.

The filter pack should not contain more than two colors of the subtractive filters (yellow, magenta, or cyan). When all three colors are in the filter pack neutral density results. Neutral density only increases the exposure time required. Neutral density is eliminated by removing the filter color of least density completely and then removing the same amount of density from each of the other two colors. Thus, if you calculated the filter pack to be $30M + 20Y + 10C$, you should remove 10 CCs of each color ($10C + 10M + 10Y$) completely for a filter pack of $20M + 10Y + 0C$.

When you either add or subtract filtration from the filter pack, the intensity of the light also changes. When filtration is added to the filter pack, the intensity of the light reaching the paper is less. When filtration is subtracted from the filter pack, more illumination reaches the paper. Thus you must adjust the exposure time when the filter pack is changed.

Fortunately, when dichroic filters are used, little exposure compensation is needed. When these filters are used, no correction is required when the yellow filtration is changed. Only a 1-percent change to the exposure time is required for each 01 unit of magenta or cyan

Table 12-1.—Filter Pack Adjustments for Subtractive Printing

If the color in excess is:	If possible, subtract these filters:	OR Add these filters
Yellow	Magenta and Cyan (or Blue)	Yellow
Magenta	Cyan and Yellow (or Green)	Magenta
Cyan	Yellow and Magenta (or Red)	Cyan
Blue	Yellow	Magenta and Cyan (or Blue)
Green	Magenta	Cyan and Yellow (or Green)
Red	Cyan	Yellow and Magenta (or Red)

Table 12-2.—Exposure Factors for Kodak CC and CP Filters

FILTER	FACTOR	FILTER	FACTOR
05Y	1.1	05B	1.1
10Y	1.1	10B	1.3
20Y	1.1	20B	1.6
30Y	1.1	30B	2.0
40Y	1.1	40B	2.4
50Y	1.1	50B	2.9
05M	1.2	05G	1.1
10M	1.3	10G	1.2
20M	1.5	20G	1.3
30M	1.7	30G	1.4
40M	1.9	40G	1.5
50M	2.1	50G	1.7
05C	1.1	05R	1.2
10C	1.2	10R	1.3
20C	1.3	20R	1.5
30C	1.4	30R	1.7
40C	1.5	40R	1.9
50C	1.6	50R	2.2

change to the filter pack. Normally, cyan is not a consideration because it is set at zero in subtractive printing, so neutral density is not created.

With experience, exposure adjustments can be estimated accurately when the test print is close to the desired density and color balance. Table 12-2 provides more detailed information on exposure compensations when CC or CP filter changes are made.

To use table 12-2, you must first divide the old exposure time by the factor for any filter removed from the pack. Then multiply the resulting time by the factor

for any filter added. When two or more color filters are changed from the filter pack, multiply the individual factors together and use the product.

Additive Printers or Enlargers

Additive printers operate completely opposite from subtractive printers. Color correcting may get confusing if you are operating both types of printers.

When making corrections to your filter pack on an additive printer, you should make the corrections as you

see them; for example, when your test print has too much green, you “tell” the printer to subtract green from the filter pack. When your test print has too much magenta, you “tell” the printer to add green to the filter pack, and so on.

The principles of color in theory are the same in subtractive and additive printing. The difference is that the additive printer uses the primary colors of red, green, and blue. When you make corrections on an additive printer, the printer is actually controlling the time that the additive colors are allowed to expose the paper through either pulsed-xenon tubes or CC filters; for example, when your test print has too much green and you subtract green from your filter pack, the printer is actually allowing more green light to reach the paper, which produces more magenta dye in processing. When the test print has too much magenta and you add green to your filter pack, the printer is actually reducing the amount of green light allowed to reach the paper, which reduces the amount of magenta dyes produced in processing.

Most additive printers automatically compensate and change the density when the filtration is changed; however, as in subtractive printing, you must achieve the correct density before making color corrections.

COLOR PROOF SHEETS

Once the basic filter pack is determined for a typical negative, the same exposure conditions can be used on future prints, providing the same types of film and paper are used. A proof sheet can provide a convenient aid in printing color negatives. The same technique used for making black-and-white proof sheets on an enlarger is used for making color proof sheets. Except when you are making color proof sheets, the enlarger height and lens-to-easel distance should be kept constant. When you are making an 8x10 enlargement from each negative, the same enlarger height that produces an 8x10 print should be used. When you must change the enlarger height from the negative previously printed, adjust the lens opening to compensate for the difference in illumination.

Assuming the exposure level for the contact prints is correct, exposures will be about the same when the negatives are placed in the negative carrier and enlarged. Some minor adjustments may be needed, however, to provide the highest quality print possible. Navy imaging facilities strive for a color balance within 05CC—because the “perfect” color print is very subjective. In most color prints, a slight color to the “warm” side is

more acceptable than color prints with a slight color cast to the “cold” side. This is particularly true when the subject in the photograph involves people.

Incidentally, you should not discard the test prints. Instead, write on them the actual exposure conditions and your predicted changes to the test print. These records will help you to gain the greatest practical value from past work and to develop the judgment needed for easier color printing in the future.

THE STANDARD NEGATIVE

Briefly defined, a standard negative is an average color negative that has been properly exposed and processed and makes an excellent print. In other words, it has been printed previously, and an accurate record of the filter pack required and other printer settings for a particular type of paper is available. A standard negative is used as a reference for comparison purposes. The standard negative is useful in several ways:

- Comparing the printing characteristics with those of other color negatives
- Comparing different paper emulsions
- Checking processing
- Programming color analyzers and automated printers

The standard negative is typical of the majority of negatives to be printed. When most of your negatives are outdoor shots on Kodak Gold 35mm film, the standard negative should obviously be an outdoor shot on Kodak Gold 35mm film. The standard negative must be normally exposed, normally processed through your imaging facility, and a typical subject with typical lighting; that is, the lighting ratio and light direction should be similar to most of your production negatives.

A gray card included in the image area of a standard negative is extremely helpful. The gray card can be used to determine whether the negative received the correct exposure; for example, a Kodak Vericolor III negative is properly exposed when the gray card density in the negative is between 0.65 and 0.85 when read through a red filter on the densitometer. For other types of film, consult the *Photo-Lab-index* to locate the proper density measurements. When used in a standard negative, the gray card must receive the same exposure as the subject.

One good practice is to have a standard negative for each general category of photographic assignments produced by your imaging facility. These standard negatives should be produced with the equipment,

light-sensitive materials, and lighting conditions commonly used in your facility; for example, when awards presentations are commonly photographed using syncro-sun techniques with a medium-format camera and Kodak VPS film, then your standard negative should be taken under the same conditions. The same applies for studio portraits, indoor on-camera flash photography, and so forth. A basic enlarger filter pack should be determined for each negative.

TRIAL-AND-ERROR PRINTING

Few characteristics are exactly the same in two color negatives. Even when the subject matter is similar, differences can be caused by normal manufacturing variations from one emulsion to another, adverse conditions before exposure, illumination of different color quality, variance in sensitivity with changes in illumination level and exposure time (reciprocity effect), adverse storage conditions between exposure and processing (latent image loss), and nonstandard processing conditions.

Most color negatives of the same subject that are exposed under similar conditions print similarly, but not identically. Differences may result from variations in lighting conditions (time of day, sky conditions, etc.), film emulsions, film processing, or other factors. These differences are normal and should be expected. The standard negative provides a good starting point for future printing requirements.

For example, you made an excellent 8x10 print from the standard negative with a filter pack of 40M + 60Y and exposed the print for 10 seconds at f/5.6. The enlarger settings should remain the same as a starting point for similar negatives, providing the same type of paper is used. For a particular production negative, you may find it necessary to add a 10M filter to the pack and adjust the printing time to 11 seconds to compensate for the differences between the new negative and the standard negative. In other words, the new negative may print differently from the standard negative by a 10M filter and a 10-percent increase in printing time.

The amount and types of color equipment you use depend on the volume of color production of the imaging facility where you work. A photo lab that makes occasional color prints probably uses only a standard negative and color printing viewing filters. Larger Navy imaging facilities that produce large quantities of custom color printing may use evaluation methods involving instruments, such as color analyzers, densitometers, and other electronic devices.

COLOR ANALYZERS

Color analyzers operate by comparing a standard negative to production negatives. For successful negative evaluation, the reference areas must have the same subject matter in all the negatives; for example, a gray card included in the picture, a flesh tone, the highlighted area of an aircraft wing, or a neutral area of a ship, all provide a suitable reference area. In portraiture, a medium-flesh tone is often selected. In other fields of photography, you should either include a gray card in the scene or expose an additional negative replacing the subject with a gray card. In the latter case, the negative with the gray card is used only for evaluation purposes and is replaced by the subject negative when the print is made.

When a skin tone is used instead of a gray card in portrait negatives, the color analyzer tends to reproduce all skin tones the same as the standard negative regardless of variations in skin color or lighting. Similarly, all images of a gray card tend to be printed alike regardless of the position of the card relative to the main light.

Color analyzers are used to reduce the waste that is produced through the trial-and-error method of color printing. The standard negative is used as a reference when color analyzing instruments are used. There are two categories of color analyzers: off-easel and on-easel.

Off-Easel Analyzers

Off-easel color evaluation is performed by measuring or evaluating the color negative before it is placed in the enlarger. Commonly in Navy imaging facilities, off-easel evaluation is accomplished using a densitometer. The main advantage of using a densitometer is you can service a number of enlargers. That is especially useful when you cannot have on-easel analyzers for each color enlarger. Another advantage, off-easel evaluation can be done under normal room lighting conditions.

To set up an off-easel evaluation system, you must first read the density of the reference patch from your standard negative on a *transmission densitometer*. You read the reference patch through a red, green, and blue filter. The densitometer provides you with direct density reading of the cyan, magenta, and yellow dyes present in the reference patch. The values that you read from the reference pack are then added to the known standard negative filter pack of the enlarger. The production

302.261

Figure 12-5.—On-easel color analyzer.

negative to be printed is then read on the densitometer and these densities are subtracted from the total density values of the standard negative (negative reference patch and enlarger filter pack). This method of evaluation does not indicate directly the required exposure for the production print, but the production print exposure can be estimated closely by using the standard negative exposure and compensating for any changes to the filter pack. An example on how this off-easel evaluation system operates is as follows:

Gray patch of standard negative	=	47C 51M 50Y
Established filter pack for standard negative	=	0C 47M 34Y
Sum:		47C 98M 84Y
Subtract gray patch of production negative		-44C 63M 49Y
Difference:		03R 35G 35Y
To illuminate neutral density	-	03 03 03
Production negative filter pack		0C 32M 33Y

A reflection densitometer also can be very useful in color print evaluation. A reflection densitometer can be

used to match an earlier printed print with the color print you are currently printing. To use a reflection densitometer as an aid in color printing, you must compare or read a reference area on your test print. This is particularly useful when you are making a color print with neutral areas. As you know, black, gray, and white have approximately equal portions of red, green, and blue. By taking a reflection densitometer reading directly from one of these neutral areas (such as a gray card, the side of a ship, or part of a gray aircraft), you can determine what color and the amount of that color in excess. To change your filter pack for print corrections, you must take one half of the density value as read from the densitometer and either add or subtract that value from your filter pack; for example, you take a reflection densitometer reading from a gray patch on your color test print. Your density readings are 50R, 50G, and 70B. The densitometer indicates that your test print is high by 20B (too much yellow dye). To adjust the filter pack, you should add CC10Y to your filter pack for subtractive printing or add CC10B on an additive printer.

Another off-easel color evaluation system is a *color video analyzer*. This system scans the color negative and is viewed directly on a color monitor. The image on the monitor can be manipulated until the proper color balance, density, and image size are achieved. The

corrections are then sent through a translator device to the printer. This system has essentially been replaced with electronic darkrooms at Navy imaging facilities.

On-Easel Analyzers

An on-easel color analyzer (fig. 12-5) is an electronic photometer used to measure the illumination and three color primaries of light on the baseboard of the enlarger. These photometers take these measurements through tricolor filters.

On-easel measurements are made conveniently by placing a small probe on the reference area of the projected image on the baseboard. This small probe is connected to a fiber-optic light tube that carries the light from the reference area to the body of the photometer.

Color analyzers are programmed using standard negatives printed by the trial-and-error method of color printing. Once a good color print is made from the standard negative, the image luminance of the master negative is measured from the reference area. This reference area is read through red, green, and blue tricolor filtered sensors and finally without filters over the photocell. The analyzer scale is then zeroed for each condition. You then insert the new production negative in the enlarger and place the photocell on the same projected reference area on the easel. The aperture and dichroic filters are then changed until the meter is zeroed out once again.

Most on-easel color analyzers have a number of memory channels so you can store programs for different film or paper types.

The advantage of on-easel color analyzers is that, unlike off-easel evaluation, each measurement compensates for filter fading, lamp aging, and different image magnifications. Exposure and filtration are given directly. A disadvantage is that the readings must be made under the same conditions as color printing on an enlarger (complete darkness except for the illumination of the projected image of the enlarger). Both on-easel and off-easel evaluation depend strongly on accurate readings and placement and choice of a good reference area.

Two methods of electronically aided color evaluation are used. They are spot or small-area measurements and large-area or integrated measurements. Small-area measurements made on the easel are the most accurate; however, a small-reference area is not always possible.

When small-reference areas are not provided, large-area measurements can be taken. Large-area measurements are made usually from the whole negative area. For off-easel evaluation using a

Courtesy of Kreonite Inc.
302.262X

Figure 12-6.—Kreonite color processor, Model KCP-16.

densitometer, a large photocell is used to take such readings. For on-easel analyzers, the image is integrated by placing diffusion material between the negative and the photocell. You then place the photocell and sample various areas of the projected image. These sample areas are then “integrated” to gray as though they were a typical subject. This type of evaluation does not compensate for images that do not contain typical color or tonal distributions; for example, when the subject of a negative is predominantly red, an integrated reading overcompensates and a cyan print results. That is called *subject anomaly* or *subject failure*. This is the method used by many automatic printers. Color prints, such as these, must be color corrected manually.

COLOR PRINT PROCESSING

Color printing paper must be handled and processed in complete darkness because color paper is panchromatic. Like color film, time and solution temperature is much more critical than in black-and-white processing. Because the processing of color paper must be very consistent, color prints are not processed in trays. Color paper is always processed in automatic color print processors (fig. 12-6) or rotary drum processors.

The chemistry most commonly used in the Navy for color paper processing is Kodak Ektacolor RA Chemicals for Process RA-4. The RA-4 process is a washless process that consists of color developer, bleach/fix, and stabilizer. The total processing time for the RA-4 process is about 4 1/2 minutes.

MAKING TRANSPARENCIES FROM COLOR NEGATIVES

You can make brilliant color transparencies from color negatives as easily as you made color reflection prints by using color printing materials on a transparent film base. These transparencies are of excellent quality. This allows you the option of making them larger, smaller, or the same size as the original negative.

Several materials are available for making color transparencies from color negatives. Two of the most common are Kodak Duratran RA and Kodak Duraclear RA display materials. These materials allow you to make large-display transparencies from color negatives.

The Kodak Duratran RA and the Duraclear RA transparency materials can be printed using the same methods, printing equipment, and processing chemicals as Duraflex RA print paper. Both the transparencies and paper are processed using Kodak Ektacolor RA-4 chemicals; however, the transparency materials require a longer processing time. The Kreonite Model KCP-16 allows for this longer processing time. By flipping a switch, you can slow down the processor, allowing for a longer processing time.

When printing color transparency materials, you must use a black easel. Because these materials do not have a paper backing, light is transmitted through the material and reflects back when a black easel is not used. All other printing steps are the same in printing color paper and color transparency materials. Consult the *Photo-Lab-Index* for starting exposure and filter pack settings.

COLOR PRINTS FROM COLOR TRANSPARENCIES

Color prints can be made directly from color transparencies (slides) without the time and expense of making an internegative, but the quality of a print can only be as good as the quality of the transparency from which the print is made. Originals that are poorly exposed or processed or are damaged or dusty do not provide satisfactory prints.

Transparencies that are old or stored under adverse conditions are likely to fade to some degree. This fading may not have been equal overall. That can create problems in printing. Generally, slide duplicates vary widely in quality and do not make high-quality color prints.

There are several direct positive materials available for making color prints directly from color slides. Kodak Ektachrome 22 paper is a reversal color paper that, when exposed to a slide, produces a positive color image of the slide. Kodak Ektachrome 22 paper is processed in Kodak Ektachrome R-3000 chemicals. Consult the *Photo-Lab-Index* for the most updated information concerning these processes.

Another way to make full-color prints directly from color transparencies is by the dye destruction color process. At the time this training manual was written, *Cibachrome* products are the only direct positive color materials manufactured using this process.

Cibachrome silver-dye-bleach materials consist of a white opaque support, coated with light-sensitive emulsion layers on one side and a matte, anticurl gelatin on the opposite side. This white pigmented plastic film base has a similar appearance to paper but is actually a film, much like color slide materials-the emulsion layers are arranged in the same order as color transparency (slide) materials (including the yellow filter layer).

Unlike conventional color paper processes where dyes are formed from color couplers during processing, dyes in Cibachrome materials are incorporated in the blue, green, and red light-sensitive layers during manufacturing. These cyan, magenta, and yellow dyes are designed to be destroyed when processed. Red exposure is intended to cause the destruction of cyan dyes, green exposure leads to the destruction of magenta dyes, and blue exposure sets up the destruction of yellow dyes.

The processing of Cibachrome materials involves four chemical steps: black-and-white developer, bleach, fixer, and stabilizer. In the black-and-white developer, the exposed silver halide crystals are reduced to metallic silver. When the silver halides in the emulsion layers are converted to metallic silver, the dyes present in the emulsions are fragmented. In the bleach, the silver image is converted back to silver salts (halides), and the dye fragments are made either colorless or water soluble. The unwanted silver salts (halides) are then removed in the fixer. The stabilizer keeps the remaining color dyes more permanent.

The principles of making color positive prints from color transparencies are the same whether coupler development or dye destruction materials are used. Colored filters are used to alter the printing light to obtain proper color balance, much the same as is done in printing color negatives.

You must keep in mind, however, that you are working with color positive materials, and not negative materials. The borders of these positive materials are black when unexposed. Dust particles and scratches also appear black. To make a test print lighter, you must increase the exposure. Dodging darkens selective areas of a print, and burning in lightens selective areas of a print. Color corrections are performed the same as the visual appearance requires.

AUTOMATED PRINTERS

Many Navy imaging facilities have automated printers that print photographic negatives. Most can be used to print both black and white and color. When high-volume production is routine in an imaging facility, automated printers are an invaluable piece of equipment.

There are many types of automated printers throughout the fleet. Some types hold long rolls of photographic paper that must be taken out and processed through a processor. Other more sophisticated types analyze, expose, cut, process, and dry the paper automatically.

ROLL PAPER PRINTERS

The roll paper printer is very popular on larger ships and shore stations that produce a large volume of color prints. The advantages of roll paper printers are they are operated under normal room lighting conditions, and they are very useful when a large number of the same size prints are needed from a single negative. When these printers are used, the correct density and color is accomplished by making test prints. Once the corrections and number of prints required are keyed into the printer, the printer makes each exposure and advances the paper automatically. When the printing is completed, the exposed roll of paper is removed and processed. After processing, the prints are then cut from the roll with a paper cutter.

Roll paper printers have built-in analyzers. These analyzers are calibrated using standard negatives. When a production negative is printed, the machine refers to the memory and produces a print using the information stored from the standard negative. Generally, that produces a print that closely represents the original

PH1 Slaughenhaupt
302.263

Figure 12-7A.—Front view of Pako BC 24 roll paper printer.

scene; however, test prints are still made to produce the highest quality prints possible. The most popular roll paper printer used in Navy imaging facilities is the Pako BC 24 (fig. 12-7A and fig. 12-7B).

MINILAB SYSTEMS

Minilab systems (fig. 12-8) have become very popular in Navy imaging shore facilities and aircraft carriers. These types of printers are fast and can be used to rush production. In these systems, the printer and processor are combined into one unit. The printer cuts the paper to size, exposes it, and automatically feeds it through the processor. Minilabs (as they are called) are used in all of the “One Hour” photo-finishing shops that you see today.

The operation of a minilab is very easy once you become familiar with the system. Minilabs can be operated under normal room lighting conditions. The printer is controlled by a keyboard (fig. 12-9). Some systems have zoom enlarging lenses to alter the image size. The negative can be aligned and composed by adjusting the negative carrier. These adjustments to the image size and cropping can be seen on a viewing screen.

PH1 Shughenhaupt

302.265X

Figure 12-8.—Noritsu QSS-1201 minilab system.

302.266

Figure 12-9.—Keyboard of a Noritsu Model 1001 print processor.

Minilabs have a microprocessor that stores information put in by a programmer. The information is retrieved through channels. The channels are programmed for different film manufacturers, ISOs, negative sizes, print sizes, and paper combinations. The various information combinations that are stored in these channels are used to print production negatives; for example, a 35mm Kodacolor negative to a 4x5 print is printed on one channel, and 35mm Fujicolor negative to a 5x7 print is printed on another. By programming different negative and print combinations into separate channels, you are able to produce production prints which have good density and color balance from the automatic printer. You can also fine-tune the density and color by using the keyboard.

Color correcting on a minilab is less complicated than on an enlarger. The keyboard of the printer contains yellow, cyan, magenta, and density keys. These keys range in value so you can make minor or major adjustments. When the density of the print is off, density can be either added or subtracted. When a production print has too much cyan, yellow, or magenta, these colors are subtracted. When the print has too much red, green, or blue, the complement of these colors is added.

After the prints are exposed, the paper is fed automatically into the processing section of the minilab. The processing section contains chemical tanks and a dryer section. Each tank has a roller assembly rack that transports the print through the processor. Minilabs require no plumbing or drains because they use a washless process, such as KodakRA-4 chemistry. When Kodak RA-4 chemistry is used, the total processing time is completed in about 4 1/2 minutes.

The setting up and programming of automated printers can be complicated. You are expected to be a printer operator only. Programming the channels, density, and color balance of automated printers should be left to the more experienced imaging facility personnel.

While automated printers are very useful in controlling a high influx of production, there are disadvantages in their use. Not all imaging facilities have the space required to support automated printers. Cropping is very restricted, and dodging and burning cannot be performed. Like all machines, automated printers require maintenance. They also must be programmed accurately to function the way they are designed. Without the support and expertise of knowledgeable personnel, normal projection printing may be preferred.

CHAPTER 13

MOTION MEDIA

Motion media has gone through many technical advances in the past several years. Portable motion-video cameras have changed from cumbersome cameras and recording packs to small hand-held cameras. Reduced size, improved quality, and easier operation has, and is continuing to improve and expand motion video in all areas of the Department of Defense. Most Navy ships have closed circuit television systems for information, entertainment, and educational purposes. Motion media is distributed easily and dominates all other sources of communication in today's society. Because of this, the Navy uses this form of communication extensively to relay information.

The most common form of motion-media photography is video. Since the motion picture is the grandfather to the technology of motion media as we know it today, it is discussed briefly in this chapter.

MOTION PICTURE

The first fact regarding motion pictures is they do not move. Each image or frame of motion picture film is a separate, still photograph. These individual images or frames are normally recorded at a rate of 24 separate pictures per second. This rate can be varied to achieve certain effects. Since so little time passes between exposing one frame and the next, there is relatively little difference between pictures, even when the subject moves rapidly.

The illusion of motion in motion-picture photography is due to the natural characteristic of human vision. This characteristic of human vision is called *persistence of vision*. Persistence of vision was discovered by Peter Mark Roget, the author of the famous Thesaurus. The retina of the eye continues to perceive an image for a short period of time after the light stimulus representing the image has been removed. Usually, this "after image" lasts about 1/50 second, depending on the brightness of the image.

In viewing a motion picture, the eye continues to perceive the fading image projected from one frame as it is replaced by the next frame, and so on. In effect,

the images are momentarily superimposed in our vision, so any differences between them, however slight, are mentally noted. If these differences suggest any relative change in subject position, the apparent difference is mentally interpreted as motion. The mind translates this information into the logical deduction that whatever we are seeing on the movie screen must be moving.

CAMERAS

Since motion pictures are a series of still pictures, the motion-picture camera is basically the same as the still-picture camera. The primary difference is that it has a mechanism for taking a series of many photographs in rapid succession and at regular intervals on a ribbon of film. All cameras have the following four basic parts: a lighttight compartment, a lens or lenses, a shutter, and a film plane or pressure plate.

The motion-picture camera has two additional basic features; the film drive and intermittent action. The film drive mechanism transports the film continually from a supply spool of unexposed film to a take-up spool of exposed film. This transport takes place by means of toothed, drive sprockets. The teeth of the drive sprockets engage the perforations along the edge of the film and move the film through the camera.

The intermittent action in a motion-picture camera is caused by a pulldown claw that advanced the film one frame at a time at the film gate.

During one cycle of operation of a motion-picture camera, the following action takes place. The film is advanced by the sprocket drive mechanism. The pulldown claw or shuttle then advances the film one frame. The film is stopped momentarily and the shutter revolves once, thereby making the exposure. The pulldown claw then moves the film to the next frame for exposure. Because the film moves in an intermittent or stop-and-go manner, it becomes necessary to have a surplus or loops of film before and after the pulldown claw to help take up the

Figure 13-1.—Basic components of a motion-picture camera.

Figure 13-2.—Rotary shutter.

shock and prevent the film from breaking (fig. 13-1).

The shutter in most motion-picture cameras is a focal plane type and is called a rotary disk shutter. A rotary disk shutter is a disk that has a segment cut out, causing the shutter to have a light and dark cycle as it rotates. Exposure is made when the cutout segment of the shutter passes in front of the film. The film is advanced during the dark cycle (fig. 13-2).

A motion-picture camera is used to photograph action in a rapid succession of still pictures on a long strip of film. Each picture area on a motion-picture film is called a frame, and the speed that the camera is operated is called frames per second (fps). The standard operating speed for 16mm cameras is 24 fps. When the camera operating speed and the rate of projection are the same, the action looks normal; therefore, the standard projection speed is also 24 fps. However, it is possible, and sometimes desirable, to make motion pictures at a slower or faster rate than 24 fps. You may do this to either slow down or speed up the action on the screen. To portray a subject in slow motion, you operate the

camera at a speed faster than the standard 24 fps, but keep the projector at the standard speed. To portray a subject in fast motion, you operate the camera at a speed slower than 24 fps, and the film is projected at 24 fps. All changes to the portrayal of normal subject motion should be done by adjusting the camera speed, not the movie projector.

Camera speeds in the thousands of frames per second are used in scientific and experimental research to measure and observe such things as the fall of liquids, the speed of objects in flight, and the bursting characteristics of objects. When films shot at very fast fps rates are projected at 24 fps, the illusion of subject motion on the screen is slowed down considerably. At these speeds the viewer can study details of the subject matter and obtain research data.

Motion-picture cameras are classified according to the size (width) of the film they use. The most common motion-picture film sizes are as follows: 8mm, super 8, 16mm, and 35mm. In the Navy today, motion-picture film has almost been completely replaced with video film; however, Hollywood productions still use motion-picture film as large as 70mm.

Lenses used in motion pictures are basically the same as lenses for still photography; therefore, the information on optics presented in chapter 1 also applies to motion-picture camera lenses. The standard or normal focal length lens for a 16mm camera is 1 inch (25mm). Longer or shorter focal length lenses should be considered as long focal length (telephoto) or wide-angle lenses, respectively, depending on what size film is used. A long focal length lens for 16mm film is 38mm or longer. A wide-angle focal length lens for this camera is 13mm-17mm. Table 13-1 illustrates some typical camera and lens combinations.

FILTERS

With one exception, the use of filters for motion pictures is the same as for still photography. The effects that filters produce on motion-picture film emulsions are the same as the effects they produce on still photographic film emulsions. The one exception is the use of a polarizing filter. Camera panning should be avoided because variable darkening of the image results. The information on filters presented in chapter 3 applies to motion-picture photography as well as still photography.

Figure 13-1.—Camera Sizes and Lens F-1 Lengths

	8mm	16mm	35mm
Normal	12mm	25mm	50mm
Wide Angle	6 to 9mm	13 to 17mm	35mm or less
Telephoto	25mm and above	38mm and above	100mm and above

EXPOSURE CALCULATION AND CONTROL

Exposure meters for measuring incident light can be used directly to help determine lighting ratios. A gray card is used to get an accurate exposure reading whenever reflected light meter readings are taken.

Incident light exposure meters are very useful for motion pictures because they can be used at a scene to calculate exposure before the subject arrives. They also can be carried throughout the scene, thereby indicating uneven lighting or “hot spots,” thus indicating whether the lighting should be altered.

With a motion-picture camera, the final exposure adjustment is usually made only with the aperture because fps rate of the camera determines the shutter speed. The goal of exposure control for motion pictures is to produce **consistent** and **uniform** image densities and tones from one scene to the next.

Accurate and correct exposure control can be achieved only through the proper use of a good exposure meter. The exposure time for a movie camera is a result of the rate at which the camera is operated (usually 24 fps) and the shutter degree opening (the degree of the open segment of the shutter). The shutter degree opening for a particular camera is provided by the camera manufacturer. Given the shutter degree opening, you can determine exposure time by use of the following formula:

$$\frac{\text{Shutter Degree Opening}}{360 \times \text{fps}} = \text{Exposure Time in Seconds}$$

For example, suppose you have a camera with a shutter degree opening of 175 degrees and you intend to be filming at the standard rate of 24 fps. Determine the shutter speed as follows:

$$\frac{\text{Shutter Degree Opening}}{360 \times \text{fps}} = \frac{175}{360 \times 24} = \frac{175}{8640} = \frac{1}{49}$$

or 1/50 second

NOTE: 360 is a constant factor (number of degrees in a circle).

The information on exposure provided in chapter 4 applies equally well to motion-picture photography as it does to still photography.

Neutral density filters (ND) are often used in motion-picture work to help control exposure because of the limited f/stop and shutter speed combinations available on motion-picture cameras. When you are shooting a movie, the fps and the shutter degree opening are fixed. You may not be able to open up the aperture to get the correct exposure control and depth of field; therefore, you would use an ND filter to reduce the amount of light reaching the film. Remember, because of the fps rate, you are restricted to a given shutter speed, and stopping the lens down would destroy your depth-of-field effect.

MOTION VIDEO

Videotape recording has basically replaced motion-picture film making. Motion video has a number of advantages compared to motion-picture coverage. Some of these advantages are as follows:

- A videotape camera can record black and white as well as color.
- No time-consuming film processing is required and recordings can be played back immediately.
- When necessary videotape may be partially or completely erased and used again for several more recordings. It can be played back numerous times and may be stored indefinitely.
- Videotape is edited or assembled more quickly than film.
- Videotapes are duplicated and distributed easily to other Navy activities.

A video camera is optically similar to a movie camera, except it does not use film. Considering the

technical complexity of a video camera, it is fundamentally simple. To understand clearly motion video, you must be familiar with some key terms. These terms will be seen commonly in all publications pertaining to video.

KEY TERMS

AGC-Automatic gain control. Regulates the volume of the audio or video light levels automatically within a camcorder.

Analog-An analog signal that fluctuates exactly like the original stimulus (examples, sweep second-hand clock, phonograph player).

Ambient Sound-Background sound or “wild” sound. Sound that surrounds the scene or location, received by the microphone and recorded onto magnetic tape.

Aspect Ratio-The ratio of the height to the width of the film or television frame. Three units high to four units wide (3:4).

Audio Track-The area of a videotape that is used for recording audio information.

Beam Splitter-An optical device within a color camera that splits the white light into three primary colors: red, green, and blue.

Camcorder-A portable video camera with videotape recorder (VTR) and a microphone attached to form a single unit.

Capstan-An electrically driven roller that rotates and transports the videotape past the recorder heads at precise and fixed speeds.

CCD-Charged-coupled device, also called a chip. A small, solid state (silicon resin) imaging device used in a video camera instead of camera pickup tubes. Inside the chip, image sensing elements translate the optical image into a video signal.

Character Generator-An electronic device used to create words or graphics that may be electronically inserted or “keyed” over the video picture.

Color Bars-A color standard used by the television industry for the alignment of cameras and videotape recordings.

Component-The processing of RGB (red, green, blue) channels as three separate channels.

Composite Signal (Y/C)-(Also called NTSC signal) The video signal in which luminance “Y” (black

and white) and chrominance (red, green, blue) and sync information are encoded into a single signal.

Control Track-The area of the videotape used for recording the information necessary to synchronize the all elements during playback.

Digital VTR-A videotape recorder that translates and records the analog video signal in digital form.

Dub-Duplication of an electronic recording. Dub is always one generation away from the original recording.

Dropout-A loss of part of the video signal, which appears as white glitches. Caused by dirty VTR heads or poor quality videotape.

Field-Scanning lines in one-half of one video or television frame. There are two fields (one odd and one even) in a frame. One field equals 262.5 scanning lines, which create a total of 525 standard television lines or one frame. Also known as the NTSC signal (U.S. TV system).

Frame-The smallest unit in television or film, a single picture. A complete scanning cycle of the two fields occurs every 1/30 second. A frame equals 525 scan lines.

Gain-The level of amplification for a video or audio signals. Increasing the video gain increases the picture contrast.

Generation-The number of dubs or copies away from the original recording. The greater the number of generations, the greater the loss of picture quality.

Heads-A small assemble within an audio or video recording system, which can erase, record or playback the signal in electromagnetic impulses.

Helical Scan, or Helical VTR-(Also called slant track). A videotape recording or a videotape recorder in which the video signal is put on tape in a slanted, diagonal way. Because the tape wraps around the head drum in a spiral-like configuration, it is called helical.

Noise-Unwanted sounds or electrical interference in a audio or video signal. In the audio track, there is a hiss or humming sound. In the video picture the interference appears as “snow.”

NTSC-National Television Standards Committee. U.S. standards for television or video signal broadcasting. Also known as the composite signal (Y/C).

Pickup Tube-The imaging device in a video camera that converts light into electrical energy (video signal).

Pixel-The smallest single picture element with which an image is constructed. The light-sensitive elements in a CCD (chip) camera.

Preroll-To start a videotape and let it roll for a few seconds before it is put in the playback or record mode so that the electronic system has time to stabilize.

RGB-The separate red, green, and blue color (chrominance), or "C," video signals.

Slant Track-Same as helical scan.

Time Base Corrector (TBC)-An electronic accessory to a videotape recorder that helps make playbacks or transfers electronically stable. A TBC helps to maintain picture stability even in dubbing-up operations.

Video Cassette-A plastic container in which a videotape moves from a supply reel to a take-up reel. Used in all but the 1-inch VTRs.

VTR-Videotape recorder or recording. Includes video cassette recorders.

Y/C-The separate processing of the luminance (Y) and chrominance (C) signals.

VIDEOTAPE RECORDERS

Videotaping is similar to audiotape recording. The electronic impulses of television pictures (video signal) and sound (audio signal) are recorded on the videotape by magnetizing the iron oxide coating on the videotape. During playback, the recorded video and audio signals are converted again by the television set into television pictures and sounds. However, the amount of electronic information is many times greater for video than for audio recording.

RECORDING SYSTEMS

There are many different systems of treating and recording the video signals. Videotape recording systems can be divided roughly into three subsections: analog and digital; composite (Y/C), and component; and tape formats.

Analog and Digital Systems

Both analog and digital systems are used in naval imaging facilities. The analog system is easier to understand if you think of it in the same terms as a record and a phonograph. Analog systems record the continually fluctuating video signal that is created and processed by a video source (camera) on videotape.

During playback, the recorded information is retrieved as an identical, continually fluctuating signal from the videotape.

Digital-video systems work on the same principle as compact disks (CD) used in your home stereo or office computer. Digital-video systems convert the analog video signals by sampling (selecting parts of) the scanned image. It then translates the scanned image into millions of independent, fixed, values called **pixels**. A pixel is the smallest single picture element from which images are constructed. Each pixel has its own color (hue and saturation) and luminance values. These values are expressed as binary numbers (series of zeros and ones). The binary numbers are then stored on, and retrieved from, videotape or other storage mediums, such as large-capacity disks.

Composite (Y/C) and Component

Composite (Y/C) and component all refer to the way the video signal is treated in the videotape recorder. A composite video signal means that the luminance information ("Y" signal), chrominance information ("C" signal), and the sync information are combined into a single signal (Y+C+sync). Standard television information is designed to operate with composite video signals. Only one wire is required to transport a composite video signal. This composite signal is usually called NTSC, because the electronic specifications for a composite video signal were adopted by the National Television Standards Committee.

The major disadvantage of a composite signal is that slight interference exists between the chrominance and luminance information. This interference becomes more noticeable through each videotape generation.

In a true component system, the R, G, B channels are kept separate and treated as separate red, green, and blue video signals throughout the entire recording process. Each of the three signals remains separate even when laid down on the videotape. The component system requires three wires to transport a video signal. This means that all equipment used in the component system requires three wires to handle the video signal that is incompatible with the NTSC system.

When the video is going to be televised, the signals of the Y/C and component systems must be combined into a single NTSC composite signal before it can be broadcast.

Figure 13-3.—Basic principles of a motion-video camera.

Tape Format Systems

The classification of a videotape recorder VTR by tape width was particularly important in the earlier days when the quality of the videotape recording was directly related to the tape format. The old standard used to be, the wider the tape, the higher the quality of the recording. Anything smaller than the 1-inch videotape was considered small format and inferior in quality. Today, 1/2-inch Betacam SP can provide equal or superior quality compared to the large-format, 1-inch machines. The Hi8 video camera (8mm) is superior to the 1/2-inch VHS cameras. Today, “small format” is used mainly to describe small, highly portable television equipment, such as small camcorders. Like all state-of-the-art electronic equipment, smaller no longer implies inferior quality.

The quality of the tape itself has much to do with the quality of the picture. No matter how sophisticated the video hardware, the resulting picture is only as good as the videotape being used.

Videotape is a ribbon of polyester film base coated with magnetic iron-oxide particles. The surface of the tape, or emulsion side, that faces the video recorder heads is highly polished to maximize tape-to-head contact and to minimize wear on the heads.

Head clogging results when oxide comes off the tape and gets caught in the head gaps of the recorder. If the tape clogs the video recording heads, you cannot play back or record. Normally, the heads will clog after recording or playing back half a dozen or so tapes. You should have the heads cleaned according to the manufacturer’s recommendations or according to Planned Maintenance System (PMS) requirements.

Videotape dropout occurs when a piece of magnetic oxide or coating on the tape flakes off or is rough, causing a “hole” or line of missing information in the picture when it is viewed on the monitor. Dropout

appears on the TV screen as little black or white lines, darting across the picture. The main causes of dropout are dirty heads or imperfections in the tape. Once dropout occurs, it cannot be replaced or corrected on the tape.

There are no black-and-white or color videotapes. Any videotape will record either black and white or color. Black and white or color depends solely on whether the camera and monitor are black and white or color.

THE VIDEO CAMERA

Refer to figure 13-3 to help clarify how a video camera operates. In the video camera, an image (a) is gathered by the camera lens (b), and focused on the face of the camera pickup tube (photocathode) or a solid-state imaging device (c). The face or screen of the photocathode is covered with thousands of light sensitive dots. As light from a particular part of the scene falls on each dot, the dot becomes electrically charged. A charge pattern is built up proportionally to the brightness of the scene. An electron beam in the pickup tube emits a steady beam of electron particles. This electron beam scans the charged pattern on the photocathode and reads over it in a series of lines. The scanning beam neutralizes each picture element or dot and produces varying electrical currents (the video signal). These currents are proportional to the charge pattern which are proportional to the light transmitted through the lens.

The current or video signal (picture) is amplified (d) and then recorded on tape by rotating heads (e) and then converted back to visible screen images in the viewfinder (f).

As each dot on the tube screen is scanned, the dot gives up its information and is wiped clean so the tube screen can respond to any new light it receives.

Figure 13-4.—Video scanning.

Figure 13-4 illustrates how this scanning process takes place. The electron beam first scans all odd-numbered lines, from left to right (a). When all odd-numbered lines have been scanned, it makes up a field. One field consists of 262.5 lines. After the odd-numbered ones are scanned, the beam jumps back to the top of the screen. At this point, the beam is so weak that it does not affect the screen. Back at the top of the screen the beam starts scanning the even-numbered lines (b). When all even-numbered lines are scanned a second field is formed. The two fields make up a frame (c) or one complete television picture. A frame consists of 525 lines. After completing a frame, the beam returns to the top to start with another first field.

This charge-forming-and-scanning is a fast, continuous process. The complete camera tube screen (frame) is scanned 30 times per second.

The motion-video camera picks up reflections of light from the scene while the microphone picks up sound. At the same time, the camera changes the light reflections into electrical impulses, and the microphone changes the sound into electrical impulses.

This is basically the way a black-and-white video camera works. A color video camera works on the same principle; however, a color video camera has three tubes. Through the use of a beam splitting device and filters, one tube forms a red image, a second tube forms a green image, and the third tube forms a blue image. The three tubes have identical scanning patterns, so the picture signals they produce are identical, except they differ in color.

During a video recording, the videotape moves past a rotating **head** that “writes” the video and audio signals on the videotape. During playback, the rotating head “reads” the magnetically stored information off the tape. Some VTRs use two or four heads for their record/play (write/read) functions. Digital VTRs have even more

Figure 13-5.—Helical scanning system.

read/write heads. For explanation purposes a VTR with two record/play heads is discussed in this chapter.

Helical, or Slant-Track, System

The two heads are mounted opposite each other, either on a rapidly spinning head drum or on a bar that spins inside a stationary head drum. When the bar spins inside a stationary head drum, the heads contact the tape through a slot in the head drum. The tape is wound around the head drum in a slanted, spiral-like manner. This permits more tape area to contact the head, allowing the transfer of large amounts of video information (fig. 13-5). If the head contacted only the width of the tape, extreme tape or drum speed would be necessary. Because the Greek word for spiral is helix, this tape wrap, and often the whole video-recording system, is called the helical scan, or slant track

Figure 13-6.—Basic videotape track system.

Most videotape recorders put at least four separate tracks on the tape: the **video track** that contains the picture information, two **audio tracks** that contain all sound information, and a **control track** that controls the videotape and rotation speed of the video heads (fig. 13-6).

VIDEO TRACK.—When video signals are recorded in the normal NTSC composite configuration, one pass of the head records a complete field of video information (Y+C). The next pass of the head, (or, if you have a two-head machine, the second head) lays down the second field right next to it, completing a single video frame. Two fields make up a single frame. The two heads must “write” sixty tracks (thirty frames) for each second of NTSC video. In the four-head VTR, one pair of heads records at normal tape speed and the other pair records at a slower speed.

AUDIO TRACK.—The audio tracks record the audio signal. They are usually recorded by fixed recording heads that are near the edge of the tape and run along the length of the videotape. Because of the demand for stereo audio and for keeping certain sounds separate even in monophonic sound, all VTR systems provide at least two audio tracks.

CONTROL TRACK.—The control track contains evenly spaced blips or spikes, called the **sync pulse**, that mark each complete television frame. These pulses synchronize the tape speed and the rotation speed of the recording heads. This allows the tape to be played on a similar machine without picture breakups. Because the control track marks each frame of recorded video, it also aids in videotape editing.

Hi8 Track System

Because space is so limited in 8mm videotape, these systems squeeze the automatically generated **time code** and other data between the video and audio portion of a single-slanted track. The time code has been developed to provide a precise editing reference by recording the

exact frame address onto the tape. The 8mm time code is digitally recorded by units of hour, minute, second, and frame by the video heads. The 8mm time code is used only for 8mm format and is not compatible with other recording formats.

The Hi8 VTR splits each slanted track into audio frequency modulation (AFM) and video information. It also uses a pulse code modulation (PCM) audio track. The audio technology used in an Hi8 VTR is superior to video home system (VHS). The video/AFM audio track and the PCM audio track are separated by the time-code data (fig. 13-7).

VIDEO MONITOR

For viewing purposes, you must playback the recording either to the transmitter or directly to a receiver (TV set or monitor). At the receiver, the video and audio signals are separated and processed by separate circuitry. This circuitry changes the video and audio signals back to sound that you can hear and pictures that you can see. The sound is reproduced at the loudspeaker, and the picture is reproduced on the face of the cathode-ray picture tube.

A primary part of the monitor system is the cathode-ray tube. A type of cathode-ray tube is used in

Figure 13-7.—Hi8 VTR tracks.

Figure 13-8.—Hi8 video camera. 302.291X

the camera to convert light rays into electrical impulses. The cathode-ray tube converts the electrical impulses back into light in the receiver (monitor).

CAMCORDERS

As a nonspecialized Photographer's Mate without a motion-media NEC 8143, you will be concerned mostly with recording motion-video images using a single camcorder. A camcorder has a single VTR directly attached to the camera to form a camera and recorder unit.

Each camcorder comes with manufacturer's instructions on how to use the equipment. Because there are a great variety of camcorders in the Navy, you must consult the instruction manual supplied with your machine for best results. One common motion-video camera used in the Navy is the Hi8 video camera (fig. 13-8).

The Hi8 camcorder is a small camera-VTR unit that records amazingly high-quality pictures and sound compared to a video home system (VHS) camcorder. It uses a special 8mm (about 1/3 inch) cassette with metal-oxide coated tape. These tapes are similar in size to an audio cassette tape.

A tempting practice while operating a camcorder is to shoot all videotape in the automatic mode. On the Sony Hi8 camcorder, when the AUTO LOCK switch is set, the iris, focus, white balance, sensitivity, and shutter speed (1/60) are set and adjusted automatically. If left unnoticed, there are several circumstances under which the AUTO LOCK mode will produce poor or undesirable results. You, as the camera operator, must pay attention to the subject and the surrounding

situations to produce quality motion-video coverage; in particular, brightness levels, focusing, color temperature of the light source, and subject movement.

Brightness Levels

The single greatest influence on picture quality is the brightness level. When the brightness level is too low, the recorded image looks grainy and flat. By familiarizing yourself with the brightness level of the subject, you can improve your recordings tremendously. In situations where the light level exceeds 100,000 lux, such as snow-covered scenes or a beach scene on a clear summer day, an ND filter is required. Under other daylight and bright, indoor conditions, the automatic iris is capable of adjusting to provide excellent results; however, in a low-light situation, such as spaces onboard ship, auxiliary lighting may be required to provide clear, sharp images. Another alternative, when available on your camcorder, is to increase gain. By increasing the gain, you increase the level of amplification of the video signal. This increases the contrast and provides a higher-quality recorded image.

In some situations, such as high-contrast scenes or backlit subjects, you must adjust the iris manually. Just like the aperture on a still camera, when the subject is backlit, open up the iris. When the subject is too bright, you must close down the iris.

Manual Focusing

There are situations when you must manually focus the camcorder to obtain sharp images. In the autofocus mode, the system uses a sensor at the center of the viewfinder screen to adjust the focus automatically; therefore, in situations where there is insufficient light, the subject is strongly backlit, or with subjects consisting of flat colors or little contrast (such as bulkheads or the sky), the autofocus mode may not function accurately.

Other situations in which you should use manual focusing are as follows:

- When the subject has finely detailed repetitive patterns
- When one subject is close to the camera and another is far away
- ◆ When the subjects are located behind screens, nets, or frosted glass
- ◆ When objects pass between the camera and the primary or intended subject

- When using lenses or filters to create special effects

You may also want to use manual focusing to conserve battery power.

CAUTION

NEVER attempt to force or manually focus the focus ring when the camera is set in the autofocus mode. This may damage the camera.

White Balance

Usually the auto white balance function of a video camera operates sufficiently in the automatic position; however, there are situations when the automatic light balance may not work correctly. Some of these cases are as follows:

- When the light reflecting from the subject is different from the light that is illuminating the camcorder
- When shooting a monochromatic subject or the subject is against a monochromatic background
- When recording under a sodium lamp, mercury lamp, or a white fluorescent lamp
- When recording outdoors under neon lights or fireworks
- ◆ When shooting scenes just before sunrise or right after sunset

To white balance a motion-video camera manually, you can follow a simple procedure. Normally a white lens cap, made of a diffuse plastic material, is supplied with the camera. You also can use any white object to white balance the camera, providing the white object is illuminated under the same conditions that you will be shooting. To white balance, you simply place the white lens cap over the lens, point the camera at the light source, and press the white balance button. Remember, when in the manual white-balance mode, if the color temperature of the light changes, you must reset the white balance.

To create special effects, there may be times when you want to "lie" to the white balance sensor; for example, you may want to produce motion video that has a warm color balance, such as that which occurs at sunrise or sunset. To produce video coverage with warm characteristics, you can "white balance" the video

camera on a blue object or any of the complimentary colors. When you record the scene, an overall yellow cast is produced. You can also use filters to create various effects.

Shutter Speed

When the Hi8 camera is set in the AUTO LOCK position, the shutter speed is set at the normal speed of 1/60 second. When fast-moving subjects are recorded at the normal shutter speed, the pictures are not recorded clearly. You can improve the image quality by increasing the shutter speed.

Because more light is required when shooting at higher shutter speeds, you should not try to shoot fast objects under poor or low-lighting conditions. Outdoors on clear days, you can record fast-moving subjects at shutter speeds of 1/2000 to 1/10000. On overcast days, shutter speeds of 1/250 to 1/1000 are recommended. While handholding the camera indoors, you may want to provide a more stable image. In this case, a shutter speed of 1/100 is recommended. Do not use a shutter speed of 1/250 or higher indoors unless you use additional artificial lighting.

CAMERA-HANDLING TECHNIQUES

In handling a motion-media camera, two words you must keep in mind are **STEADINESS** and **SMOOTHNESS**. When you are shooting motion media, the camera must be held steady, and deliberate camera movements (such as tilts, pans, dollies, zooming, and so on) must be made smoothly. When viewed, the images undergo a high degree of enlargement. Image movement caused by camera unsteadiness is distracting to the audience.

HANDHOLDING THE CAMERA

Very few division officers or chiefs in an imaging facility expect a cameraperson to shoot every scene from a tripod. Tripods cut down on maneuverability. When you are shooting uncontrolled action, "shooting from the hip" is common practice. During a fast-breaking event, it is usually the only way you can get the required coverage. When there is plenty of action in the scene, people do not notice the effects of excessive camera movement by the cameraman.

There are many occasions when freedom of movement and mobility in handholding the camera are essential. You can still produce acceptable motion-video coverage if you use your body as a camera support and

shock absorber. When handholding a camera, keep your arms in close to your body and your legs and feet spread about a shoulder width apart. Bend your knees slightly, keeping your weight on the balls of your feet. Lean your body backslightly for better balance. The camera should be over your knees for greatest stability. Hold the camera firmly against your face and place your hand in the camera strap.

Control your breathing while shooting. Each breath you take causes the camera to rise and fall slightly. The technique of taking a deep breath, exhaling a little, and holding the rest while you shoot is an effective way to help eliminate camera unsteadiness. When shooting a long scene, breathe as evenly and slowly as possible.

For added steadiness when handholding a camera, you can lean against something, such as a tree or a wall. Another method for handholding a video camera is to kneel on one leg and rest your elbow on the raised knee. When you must pan the camera, keep your elbow free and pivot your body at the waist.

When handholding a video camera, keep the following facts in mind to reduce the shakiness problem:

- Concentrate on handholding the camera steady while using a wide-angle lens. Your shakiness will be reduced considerably. When using a wide-angle lens, you must get as close to the subject as possible to provide an acceptable image size.
- Shakiness is directly proportional to the focal length of the lens. Slight shakiness may be almost unnoticeable with a wide lens. With a long lens, the same amount of shakiness destroys the entire scene. (See table 13-1.)
- Give yourself a steady platform. Before you squeeze the record button, inhale, then partially exhale. Now, squeeze. Do not pull or jerk the record button. Lean against a building, a tree, or the side of a car. Any support of this nature may provide more steadiness than free standing.

TRIPODS

A tripod can literally be considered the “basis” for most good motion-media products. To help you realize just how important a tripod is for shooting motion media, consider handholding a movie projector. You cannot hold the projector steady for any period of time. The picture weaves around on the screen and is very distracting to the viewers. The same result is created when a motion-video camera is handheld, but in this case, images within the picture area appear to weave

around because of camera movement. The image you see in the camera viewfinder is so small that you may not notice the camera movement. It is easy to think you are holding the camera steady. Bear in mind that the slightest amount of camera movement is magnified many times when the image is played back

While not all situations permit the use of a tripod, the use of a folded tripod as a unipod is preferable to shooting without camera support. Even the lightest weight, so-called “handheld” video camera produces much better results when supported adequately.

Camera steadiness is only one advantage of using a tripod. When using a tripod, you automatically take more time to compose and check scenes before recording them.

RECORDING FROM A MOVING VEHICLE

Sometimes you may have to record from a moving vehicle, such as a truck or a boat. For this type of assignment, the problem of holding the camera steady becomes even more difficult. In this situation you should handhold the camera, because a tripod transmits vibrations and movements from the vehicle to the camera. Keep your weight on the balls of your feet, and keep your knees flexed so you can sway and bend as the vehicle rolls, pitches, or bounces. Watch the horizon in the viewfinder. A tilted or wobbly horizon is very detracting when being viewed. When shooting from moving vehicles you should use a short focal-length lens and a fast shutter speed.

CAUTION

When shooting from a moving vehicle, you must follow all safety precautions. Use common sense, you do not want to jeopardize yourself or the video equipment.

PANNING

One of the most commonly abused motion-media techniques is panning. Panning is moving the camera from left to right or right to left. Moving it up or down is called tilting.

Only a few subjects require panning while you are actually taping. The use of panning can keep a moving procession, such as a marching unit in view, show a sweep of landscape, or show the relationship between objects or subjects.

There are definite and clear-cut rules and methods for panning. The very first is **PAN ONLY WHEN PANNING IS NECESSARY**. Panning a camera without a valid reason produces images that only irritate the viewer.

Making Pans

Making professional-quality pans takes practice and experience; however, you can easily gain this skill. One of the first and most important points to remember is to pan slowly and smoothly. Panning appears faster on the screen than it actually is; therefore, camera pans must be slow and consistent while maintaining a smooth, steady panning motion. When panning a moving object, you must keep pace with the object and allow for subject lead room. Panning too fast may make the viewer dizzy; therefore, it is advisable not to position the camera too close to the subject. The farther the subject is from the camera, the slower the pan required to follow the subject at a given speed.

Throughout the entire pan, the camera must be level without up and down wobbling. Whenever possible, rehearse the pan before you actually shoot. Know exactly where and when you want to start and end the pan. Practice the pan several times without recording on tape. Make the pan shot only after you can do it smoothly and accurately. The smoothest and best pans are made with the use of a tripod or other suitable camera support. Good handheld pans are always difficult to achieve.

Before you pan with a tripod, be sure the camera is absolutely level. Check the camera for level throughout the entire arc of the pan with a spirit bubble level located on top of the tripod head.

To produce better pan shots, position yourself comfortably for the end of the pan. Then, keeping your feet in this position, "wind" yourself around to the start pan position. As the pan progresses, "unwind" into the most comfortable position for a smooth stop. When using a tripod, be careful not to bump into the tripod as you are shooting.

Tilting the Camera

Moving a camera up and down vertically is called tilting. Tilting is useful when you want to photograph tall structures in one shot or to follow action, such as a parachute jumper.

Most of the rules that apply to horizontal panning apply equally well to tilting. As with horizontal panning,

tilting should be used only when stationary shots cannot accomplish the desired effect.

A tilt should be made slowly and smoothly. Know where and when you want to start and end the tilt. Usually, you start and end a tilt with a stationary shot.

To photograph a tall building or object, you should normally start the tilt at the bottom and move up. This is the way people naturally look at tall objects. There may be times, however, when you may start a tilt at the top and move down; for example, you might show flames coming out from the top-floor windows of a skyscraper, then tilt down to show the fire trucks arriving. When you are following action with a tilt, the type of action determines the direction of tilt. Also, as with a horizontal pan, you should show enough of the surrounding area so the audience can associate the subject with its location.

SHOT VARIETY

One of the great advantages of motion media is that it involves the viewers in the action. Viewers feel that they are there and participating in whatever is happening on the screen. They can be made to feel that they are moving along with the action as it develops, they become even more involved. Changes in the camera angle permit the viewers to see the same subject from several different positions, as though they were moving within the scene. This adds variety and makes the images they see more interesting because something is a little different about each one. However, be careful to keep these camera-angle changes from confusing the viewers. If the changes are so different that they seem to be in other locations, the viewers lose their orientation. When choosing the camera angle, be sure you present the subject from the best possible vantage point and create the proper psychological effect.

MOVEMENT

When you can control the angle at which the action passes across the camera lens axis, your shots will show the apparent speeding up or slowing down action. Objects moving at right angles to the lens (across the lens axis) appear to be moving faster than objects approaching the lens directly or going straight away from it. You can vary the apparent speed of objects by selecting various camera angles.

Good motion-media footage needs movement. Movement can take place in front of the camera, of the camera itself, and of course in the picture itself. The

movements necessary for good motion video are divided into three categories:

- Primary movement (movement of the subject)
- Secondary movement (movement of the camera)
- Tertiary movement (movement produced by successive shots from different cameras)

Primary Movement

Movement in front of the camera, usually that of the subject, is called primary movement. Primary movement toward or away from the camera is stronger than lateral movement. More emphasis is created by having the subject move toward or away from the camera. Exits and entrances are more impressive when they occur toward or away from the camera. Lateral movement of a subject should always be lead with the camera. The viewer wants to know where the subject is going, not where it has been.

Secondary Movement

Secondary or camera movement is normally done in television studios. Secondary movements include: pans, tilts, dollies, zooms, trucks, and pedestal movements. Secondary movements are used to follow primary movement, to change or adjust picture composition, or to emphasize or dramatize something. Secondary movements must have a valid purpose. Do not make them just for something to do.

DOLLY.-A dolly is a piece of equipment that normally requires a small crew to operate. You can dolly-in to increase the size of an object gradually on the screen or dolly-out to decrease the size of the object on the screen. Likewise, dollying decreases or increases the field of view. A zoom lens can be used for the same purpose as a dolly. During a zoom, the camera does not move; therefore, perspective does not change as it does during a dolly.

TRUCK.-A truck is a piece of equipment that is basically a tripod with wheels. The camera is used to follow lateral subject movement or you could truck the camera along the objects. In either case, camera-to-subject distance does not change.

PEDESTAL.-A pedestal is used to either raise or lower the camera. Pedestalling can provide the audience with a view looking down on the subject or up at the subject. A pedestal may also be used to compensate for tall or short camerapersons or subjects.

Tertiary Movement

Tertiary movement results from a sequence of shots from two or more cameras. When two or more cameras are used, you can select from a variety of pictures and determine which picture is to be recorded and when. When more than one camera is used, you can easily emphasize, de-emphasize, show action and reaction in rapid or slow succession. The effect of tertiary movement is accomplished through videotape editing.

COMPOSITION

Video images, like still photographs, are subject to the aesthetic rules of picture composition. There are, however, factors peculiar to video that more or less influence television composition. These factors are as follows:

- The small monitor requires objects to be shown relatively large so they can be seen clearly on a small screen. You must shoot more extreme close-ups (ECU), close-ups (CU), medium shots (MS), few long shots (LS), and very few extreme long shots (ELS).
- The 3:4 aspect ratio of the picture cannot be changed so all picture elements must be composed to fit it. The aspect ratio is the ratio of picture height to width. There is no vertical format in television. You must always think horizontal format.
- The video camera is the eyes of the viewer. Therefore, camera movement, as well as the static arrangement of elements within the frame, must be considered.
- When shooting uncontrolled action, you may not be able to predetermine composition. Sometimes all you can do is correct certain compositional errors.

In motion media, the picture on the screen is referred to as a shot. A shot is one continuous camera run from the time the recording starts to the time the recording stops. A shot may last a few seconds, several minutes, or the entire program. A motion-video cameraperson must always think in terms of shots.

Most rules of composition in still photography apply equally well to composition in motion media. Composition was covered earlier in chapter 5. The

Figure 13-9.-TV framing.

Figure 13-10.—Long shot, medium shot, and closeup shot progression.

302.210

simple line drawing examples of TV framing (fig. 13-9) indicates how to stage and show elements within the confines of the small 3:4 fixed aspect ratio of a television picture.

Use high- and low-camera angles with caution. High angles tend to shorten the legs of a person. Low angles may distort the body and face of the subject. Of course, watch for objects that seem to be growing out of or are balanced on a person's head.

Area of Talent Included

Most motion-media assignments involve people. You may find it convenient to identify people shots by the section of the body that is included in the frame. The person's head is usually in the top of the picture; therefore, shots vary according to the lowest part of the talent shown at the bottom of the screen. Thus the terms used to describe various people shots are as follows: full figure shot, knee shot, thigh shot, waist shot, bust shot, head shot, tight head shot.

Number of People Included

The shot designations that are easiest to remember are the ones that refer to the number of people included in the picture. When only one person is to be shot, it is a one-shot. Obviously, a shot that shows two people is a two-shot, three people make a three-shot, and so on; however, when five or six people are pictured it is called

a group-shot. A crowd-shot is when a large group of 20 or more people is being framed.

BASIC SEQUENCE

During motion-media recording, you can change the image size by changing the camera-to-subject distance or by using a zoom lens (which also changes the field of view).

When recording an event on motion media, there are three basic shots or sequences you must use: long shots (LS), medium shots (MS), and closeup shots (CU) (fig. 13-10). The type of shot being used can limit or increase the amount of visual information presented to the viewer. Long shots generally establish a location. A medium shot is used primarily as a transition between a long shot and closeup shot. Closeup shots create impact and provide more detail and less visual information pertaining to the subject's surroundings.

Shot classifications can be broken down into five categories: extreme long shots, long shots, medium shots, closeup shots, and extreme closeup shots.

Extreme Long Shots

An extreme long shot (ELS) is used to portray a vast area from an apparently very long distance. An ELS is used to impress the viewer with the immense scope of the setting or scene. An ELS is best usually when made with a stationary camera. Camera panning for an ELS

should be avoided unless panning is needed to show more of the setting or to help increase audience interest in the film. An extreme long shot can be used to give the audience an overall view of the setting before the main action is introduced. The use of an ELS is an effective way to capture audience interest from the start. Extreme long shots should normally be taken from a high vantage point, such as from a tall building, a hilltop, or an aircraft. Extreme long shots are used primarily in films and are seldom used in video productions.

Long Shots

A long shot (LS) shows the entire scene area where the action is to take place. The setting, the actors, and the props are shown with an LS to acquaint the audience with their overall appearance and location within the scene. An LS is used to establish all elements within the scene so the audience knows who and what is involved and where they are located. An LS, therefore, tells where. It establishes where the action is taking place.

The subject's entrances, exits, and movements within a scene should normally be shown with an LS when their locations in the scene are significant. Following actors from location to location within a scene area with closeup shots confuses the viewer about the location of the subject within the scene.

The composition for an LS is usually "loose," giving room for the subject to move about. While this may make identification of actors somewhat difficult, an LS is usually short and the subjects will be identifiable in closer shots.

Medium Shots

A medium shot (MS) is usually used between a long shot and a closeup shot. After the scene location has been established with an LS, the camera is moved closer to the main subject or a longer focal-length lens is used to bring the main element of the scene into full frame or near full-frame size. A medium shot tends to narrow the center of interest for the audience and answers the question "what."

In an MS, actors are usually photographed to show them from the waist up. An MS is normally sufficient to show clearly the facial expressions, gestures, or movements of a single actor or a small group of actors.

With an MS, movement of the subject can be followed with a pan or other camera movement while still showing enough of the surroundings so the audience does not become disoriented. Motion-media coverage should normally progress from a long shot, to a medium shot, to a close-up, then back to a medium shot. This

reestablishes the scene location or the actors within the scene.

Closeup Shots

The closeup shot (CU) fills a frame with the most important part of a scene. The CU should include only action of primary interest. The portion selected of an overall scene, such as a face, a small object, or a small part of the action, may be filmed with a closeup shot. Close-ups give the audience a detailed view of the most important part or action within a scene. Close-ups also help to build audience interest in the film. The CU shot can be used to "move" the audience into the scene, eliminate nonessentials, or isolate a significant incident.

As a motion-media cameraperson, one of the strongest storytelling devices you have are close-ups. Closeup shots should be reserved for important parts of the story so they deliver impact to the audience.

Extreme Closeup Shots

Very small objects or areas or small portions of large objects can be photographed with an extreme closeup shot (ECU), so their images are magnified on the screen. Small machine parts, such as calibrations on a ruler or a match at the end of a cigarette, can be very effective when shown on a full screen in an ECU.

Do not forget, you must change camera angles between shots within a shot sequence.

CONTINUITY

Motion media should present an event in a continuous, smooth, logical and coherent manner. When this goal is reached, the film has good continuity. Continuity plays a major role in the success or failure of a project. Without good continuity, a motion video would be nothing more than a jumbled mass of unrelated still-pictures. On the other hand, good continuity in a film encourages the audience to become absorbed in the film. Continuity then is the smooth flow of action or events from one shot or sequence to the next. Continuity is the correlation of details such as props, lighting, sound level, image placement, and direction of movement across the screen between successive shots of the same piece of action.

The shooting of all motion media should be based on a shooting plan. This plan may be as simple as a few scribbled notes, or it can be an elaborate script. The better the shooting plan, the better your chances of success in achieving good continuity. Another way you can learn to create good continuity is to watch and

analyze “Hollywood” movies. The next time you see a Hollywood production, notice how the action flows smoothly from shot to shot and from scene to scene. Try to visualize the techniques and camera angles that were used. Then, on your next assignment, plan them first, then use some of these professional techniques to achieve good continuity.

The first step toward good continuity in your films is the planning beforehand. You should plan your continuity and put your ideas on paper. Do not get the idea that all your shots have to follow a written script. News events, and other uncontrolled action, are usually shot without a script; nevertheless, you should be able to anticipate action and prepare a mental script. The information you must know before starting to shoot is what scenes and actions are needed to satisfy the requestor.

SCREEN DIRECTION

In motion-media photography, the direction a person or object either looks or moves can cause continuity problems. The direction a person or object looks or moves is called screen direction. When a look or move in a particular direction is unaccountably changed from one shot or scene to another, the continuity of the film is disrupted. Any change in screen direction must be explained or the subject may suddenly change screen direction and appear to be going the wrong way.

How the camera “sees” the action—not how the action actually appears—is important. In other words, the audience judges the action by its screen appearance, not by the way it actually appeared during filming.

There are four types of screen direction. They are as follows: neutral, constant, contrasting, and static.

Neutral Screen Direction

Neutral screen direction movement shows subjects moving toward or away from the camera. Because neutral screen direction movement is nondirectional, it may be used or intercut with scenes that show movement in either right or left directions. The following are neutral screen direction movements.

- Head-on and tail-away shots show the subject moving directly toward or away from the camera. For an absolutely neutral shot, only the front or back of the subject should be shown. When one side of the subject is shown, the shot will show some direction and not be absolutely neutral. Entrance and exit shots also show direction and therefore are not neutral.

Figure 13-11.—Showing a change in screen direction.

A shot can start as a neutral shot and transition into a directional shot, or vice versa; for example, start with a head-on shot of a car and continue filming as the car turns to the right and exits the frame, or start with a direction showing a shot of the car entering the frame from the left, and continue filming as the car turns left to a tail-away neutral shot (fig. 13-11). These types of

302.214

Figure 13-12.—Showing change of screen direction.

shots can be used to change screen direction by temporarily showing a neutral condition between two shots when the subject moves in opposite directions.

- Tracking shots are accomplished by moving the camera directly ahead or behind the subject, either leading or following the subject, respectively.

As with head-on or tail-away shots, tracking shots are neutral only when the subject is not shown entering or leaving the frame and when only the front or back of the subject is shown.

- High-or-low camera angle shots—The subject moves directly toward and under or over the camera so, the subject exits at either the bottom or the top of the frame. Examples: a train, shot from a high-camera angle, may move directly under the camera and exit at the bottom of the frame, or an aircraft may take off and move over a low-angled camera and exit at the top of the frame.

- Subjects traveling abreast shots—Two or more subjects move directly toward the camera and split up to exit the frame on both sides of the camera, or enter the frame on both sides of the camera and join up, moving directly away from the camera.

A neutral shot inserted between two shots of a subject moving in opposite cross-screen directions distracts the audience momentarily to allow for the change in direction.

To open a sequence, you can use a head-on shot to bring a moving subject from a distant point toward the audience. To close a sequence, you can use a tail-away shot of a subject moving away from the camera. Shots, such as these, present moving images that increase or

decrease in size and have more of an effect on apparent depth than do cross-screen movements.

Head-on and tail-away tracking shots add variety by offering a change from the usual three-quarter side shots. Head-on shots tend to produce greater audience impact because the audience is “placed” dead center with the action advancing toward them.

Constant Screen Direction

Constant screen direction shows subjects moving in one direction only. When one subject moves in the same direction through a series of shots, progression is represented.

Once screen direction has been established, it should be maintained until a change in direction can be explained. When a shot suddenly shows a subject traveling in the opposite direction to the previous shot, the audience will get the impression that the subject has turned around and is heading back to the starting point. Any change in screen direction must be explained.

One way to change screen direction (for example, a head-on to a tail-away) and explain the change to the viewers is to film the subject in the following sequence. First, record a head-on shot. Secondly, cut the shot to a three-quarter angle of the subject moving left to right. Next, cut the three-quarter angle to a view of the subject crossing the screen, then to a rear three-quarter angle of the subject. Finally, cut from the rear three-quarter angle to a tail-away shot (fig. 13-12).

A way to maintain constant screen direction is to use the action-axis technique. An action axis is nothing more than an imaginary line created by subject movement.

Figure 13-13.—Subject crossing the action axis.

When the camera is positioned on the same side of the action axis each time it is moved for a series of shots, the screen direction remains the same throughout the series. The relationship between the camera and subject movement or action axis remains the same if the camera does not cross the action axis. Once established, screen direction can be maintained by keeping the camera on the same side of the action axis.

When constant screen direction cannot be maintained, any change in direction **MUST** be visually explained to the audience. Constant screen direction changes can be explained in the following ways:

- ◆ Show the moving subject actually changing direction. This is the most effective way to change screen direction because the audience sees the subject change direction and there is no doubt in their minds how it took place.
- ◆ Film the moving subject crossing the action axis on a corner or curve. This permits the subject to exit the

frame on the “wrong side,” thus changing screen direction (fig. 13-13).

- ◆ Use a reaction closeup shot of an observer viewing the movement in the new direction. A reaction close-up serves as a neutral shot and distracts the audience, so the change in screen direction can take place. A reaction close-up, in this situation, could be a close-up of an observer’s head turning to follow the movement of the previous scene. The head of the observer should turn as though the action is taking place behind the camera, thus putting the camera between the action and the observer.

Contrasting Screen Direction

Contrasting screen direction is used to show subject movement in opposite directions. This can be shown by a subject moving toward a distant destination and then returning to the starting place. An example would be a sailor who leaves the ship and walks in a left to right screen direction to town. Therefore, the ship-to-town direction is established as left to right. Movement of the sailor to the right is toward the town and movement to the left is toward the ship. The viewer will associate the sailor’s walking in a right to left screen direction as returning to the ship. Once the direction of travel is established, you must maintain it.

Contrasting screen direction is also used to show opposing subjects moving toward each other. An example would be two warships that are headed into battle. The first ship is shown steaming from left to right, and the second ship is shown steaming from right to left. This pattern gives viewers the impression that the ships are closing the distance between them and will soon meet.

Static Screen Direction

Static screen direction refers to the direction that subjects look or face. Screen direction must be established and maintained even when the subject does not move about within the scene. The direction in which the subject looks should match throughout a series of consecutive shots. The direction the subject faces can be different from the direction that the subject looks; therefore, the static screen direction is the direction in which the subject is looking. To maintain static screen

Figure 13-14.—To maintain static screen direction, do not cross the action axis with a camera.

302.215

direction, the camera operator must remain on one side of the action axis (fig. 13-14).

CUT-IN AND CUTAWAY SHOTS

In filming uncontrolled action, it is almost impossible at times to film overlapping action. This is where cut shots come into play. Cut shots are extremely valuable because they provide a form of audience distraction. In addition, the cutaway can account for lapses of time and stimulate audience interest; therefore, if you shoot plenty of cutaways and cut-ins, you have passed a major stumbling block in shooting uncontrolled action. Shooting a football game is a good example of uncontrolled action; but can you imagine how boring it would be if there were no cutaways or cut-ins? An audience would soon get tired of seeing nothing but football plays. By using different scenes, you can show

just the highlights of the game and the audience will go away satisfied, feeling that they have seen the entire game.

Cut-ins and cutaways are related to the primary subject or action. They show something that may or may not have occurred simultaneously with the primary action. Both cut-ins and cutaways fill gaps between scenes where the action does not match. The use of cut-ins and cutaways can account for a lapse of time or they are used to create or enhance the mood of a film.

Cutaway shots are scenes that “cut” away from the action. Crowds, cheering fans, cheerleaders, and sideline action are all examples of cutaway shots. Ideally, cutaways should smooth out the continuity of the film, so the audience does not realize that some of the action that took place on the field has been removed from the film.

A cutaway also can be used when you want to condense an extended flow of action; for example, if you start a sequence with a closeup shot of the time clock indicating 12 minutes left in the quarter, then cut to the primary action on the field for about 10 seconds, then cut back to the clock indicating 3 minutes left—the elapsed time of 9 minutes would be indicated to the audience.

An example of a cut-in is a close-up of one player's foot as he kicks the ball. This close-up could have been shot at any time; however, by inserting the cut-in into the film during editing, the audience feels that the kick actually happened during the game.

The difference between a cut-in and a cutaway is simple. When filming the football game, the camera operator “went in” and took a close-up of the kicker's foot as he kicked the ball. The operator of the camera cut-in to the action. However, when the camera operator shoots a close-up of a fan's foot kicking another fan who had been rooting for the wrong team, that is a cutaway, because it cut away from the primary action of the game. Cutaway shots represent secondary action. Cut-in shots represent primary action.

CONTROLLED ACTION

As the name implies, in controlled action you can control all aspects of a production. This includes actors, their actions, the set lighting, and sound recording, if any. You usually work from a well-developed script that includes all the details. If the actors speak, the dialogue is in the script. If the action is described by a narrator, the narration is in the script. If the film is silent, the titles appear in the script. Examples of controlled-action films include training films, some documentaries and historical records, and many publicity or recruiting films. Controlled action, motion-media productions are produced only by personnel with specialized “C” school or university training. As a nonspecialized Photographer's Mate, you will be faced with uncontrolled or semicontrolled action elements of a production or film.

UNCONTROLLED ACTION

In a controlled-action situation, everything is normally written in the form of a detailed shooting script. Predictable filming is performed and there are few crises, except the occasional human oversights and mechanical malfunctions.

The other world of motion-video recording (uncontrolled action) is full of crises and surprises.

Success primarily is due to good reflexes, accurate guesswork, and quick thinking. Careful planning is not the most significant factor. Most of your motion-media assignments will be uncontrolled or semicontrolled action.

Your success as a maker of uncontrolled-action films depends on your knowledge of the capabilities and operation of video equipment. You must also possess a high level of technical skill. There is neither time nor opportunity for research or practice while doing this kind of assignment. You must be prepared in advance. News, sports, special events, and on site-coverage of ongoing activities make up the bulk of this type of assignment. Another class of uncontrolled action is the documentation of events that follow a known course or pattern, such as parades and ceremonies. These are called semicontrolled, because you know in advance approximately what is going to happen, even though you cannot influence it for recording purposes. Both types of assignments are challenging, exciting, and usually welcomed by confident camerapersons. But, they can be “unfortunate experiences” for those not properly prepared to cope with them.

PREPARATION FOR FILMING UNCONTROLLED AND SEMICONTROLLED ACTIONS

Obviously you cannot develop a specific, detailed plan for shooting uncontrolled or semicontrolled action. You must get as much information about the assignment as possible and in as far in advance as possible. This information helps to provide an estimate of requirements for equipment, supplies, scheduling of personnel, transportation, camera positions, lighting, and other technical details.

Whenever you are assigned to cover VIP arrivals, award presentations, or special events, you should immediately contact the person or agency in charge of the project. This person is usually the public affairs officer (PAO). The PAO can furnish you the full scope of your assignment and provide the following basic information:

- Name and rank or title of the person(s) involved
- Place and time of arrival
- Complete schedule of activities

When possible, you should personally inspect the location and route of the proposed action (site survey). If this cannot be done, try to get drawings, maps, plans, or photographs of the area. Eyewitness descriptions or

pictures of similar events also may be helpful. Ask questions about the location of the subject, the type and direction of movement, and the sequence of actions to be recorded.

With this information, you can draft a rough plan. By working closely with the project officer, you should be kept reasonably well informed and can arrange your shooting in a logical order. Be careful, however, not to “plan yourself into a trap.” Expect last minute changes in your plan, and, therefore, keep alternative plans in mind and ways they can be put into effect quickly.

Next, determine shooting requirements and the number of cameras and people you need. Check probable camera locations for the long, medium, and closeup shots. Determine the amount of tape you require, and consider the possibility of some unplanned requirements. Determine whether you will need transportation and additional equipment.

A hypothetical assignment: The lab has received the following orders: “The Chief of Naval Operations and his party are expected to arrive aboard your ship tomorrow. The flag requires complete photographic coverage of all official activities of the CNO and his party while on the ship.” The division chief has assigned you to cover the motion media.

After you check with the officer in charge of the event, you find that the CNO and his party are expected to arrive by aircraft at 1300 hours. The party consists of the Chief of Naval Operations and three aides. The purpose of this visit is to inspect the ship and to present several awards. The CNO and his party plan to depart at 1700 the same day.

With this information you can now plan your shooting outline. In an event of this kind, you cannot expect to stage or control many shots.

The following shooting outline is an example of what you might come up with:

Scene 1: Aircraft (A/C) with CNO landing.

Scene 2: Side boys, flag officer, and CO on deck in front of island.

Scene 3: A/C taxis to island.

Scene 4: CNO’s party disembarks A/C.

Scene 5: Flag officer and CO greet CNO.

Scene 6: CNO inspects side boys.

Scene 7: LS, MS, and CU of CNO presenting awards.

Scene 8: CNO makes speech

Scene 9: CNO and party tour ship.

Scene 10: CNO and party return to A/C.

Scene 11: A/C taxis to fantail for deck launch.

Scene 12: A/C takes off.

Now, how do you get the coverage?

In scene 1, you could be in a high position for an establishing shot showing the flight deck with the A/C landing. After the A/C lands, you move down to the flight deck and shoot scene 2, MS, of the side boys, the flag officer, and the CO taking their positions on deck to greet the CNO. Scene 3 is an LS showing the A/C taxiing to the island. For scene 4, shoot an MS of the CNO and his party leaving the A/C. Scene 5 is a CU of the flag officer and CO greeting the CNO. Scene 6 starts with an LS of the CNO inspecting the side boys. Circumstances permitting, move in for an MS and CU of the inspection. Scenes 7 and 8 should be easy to shoot because of the time it takes to read citations, make awards, and give a speech. This should allow plenty of time for you to move about and get long shots, medium shots, close-ups, and cut shots. Follow your judgment and intuition for shooting scenes 9, 10, and 11. Scene 12 is your closing shot. Again, shoot from a high position to show the flight deck. Pan the A/C and follow it until it is out of sight.

The shooting outline not only serves as a “program” for planning the sequence of coverage, but it also provides a basis for determining camera placement, movement, and shot framing.

RECORDING GRAPHICS

Graphics have many applications, such as title cards, cast lists, maps, tables, charts, photographs, and inserts. Graphics should not be treated casually. Without precautions, graphics can become unsharp, confusing, tilted, distorted, and incomplete. Much of the graphics and text used in motion-video productions are created on a character generator. A character generator is an electronic device used to create words or graphics and electronically inserts them over a video picture. When a character generator is not available, graphics must be recorded by a camera.

When you are shooting graphics that will be viewed on a monitor, the camera lens must be centered and parallel the graphic. The graphic and camera must be level. Your framing must be correct.

Figure 13-15.—The 3:4 ratio used for a video graphic.

Get in close enough with the video camera to show clearly all detail, but not so close that some of the information area is lost. Avoid using a wide-angle lens. Besides the possibility of camera shadows falling on the graphic, distortion is likely to occur and will be most noticeable when panning over the graphic. A longer focal-length lens overcomes the distortion problem, but is less smoothly panned.

LIGHTING

Because light reflections can obscure detail on a shiny graphic, the experienced graphic artist and photographer will avoid glossy materials and glossy photographs. However, when it is causing objectionable reflections, the graphic can sometimes be tilted slightly to help clear them; otherwise, relighting or surface dulling may become necessary. The lighting for a TV graphic is similar to lighting reflection originals in copy

work. Graphics must be flat. Unmounted, warped, or curved surfaces easily show unwanted reflections.

SAFE TITLE AREA

In the production of slides for use as television graphics, important picture information must be confined within the area of the TV monitor.

Figure 13-15 is drawn in proportion to a 35mm film frame and shows the safe title area, maximum transmitted area, and film frame.

IDENTIFYING RECORDED IMAGE CONTENT

If you were notified that you won a brand new Jaguar or Lamborgini, you would probably be ecstatic. If you were presented with a truckload of unidentified, assorted parts and told that you now had everything

COMMAND/UNIT		
CAMERA OPERATOR	CAMERA NO.	DATE
TAPE/ROLL NO.	SUBJECT	

Figure 13-16.—The slate.

required to put the new car together, you probably would not be entirely grateful. Maybe you could assemble it (if you were an experienced mechanic), but you know that more information would save you time, frustration, duplication of effort, and help tremendously toward a successful outcome. On the other hand, if every part were clearly identified and the exact relationship to every other part was unmistakably described, you would certainly appreciate the gift much more. Being faced with several thousand feet of unidentified videotape is very much the same kind of situation.

The biggest problem encountered by imaging personnel in the Department of Defense during Operation Desert Storm was the lack of identification of exposed imagery. There were literally boxes of film and videotape lining the passageways in the Pentagon. Most of this imagery was of little value because it was not identified, or it was labeled inaccurately.

Accurate records are almost as important as good video coverage in achieving a professional product. Imaging products must be labeled, so the subject matter and subject location are easily identifiable on the tape. Often, there is no opportunity for personal contact between the cameraperson and editor; therefore, records identifying the filmed image content are the only information available. Logically, the better the records, the more useful the videotape. The opposite rule is also true. Inaccurate records can make the video coverage useless. Do not let that happen to your work.

SLATING

The slate you use to identify video scenes may take several forms. In emergencies you may even write scene identification on a scrap of paper and film it before shooting the scene; however, in most instances, your slate is more formal. Your regular slate is made to show whatever information is necessary. Generally, this includes the command or unit, title or subject, name of the cameraperson (identifies who is responsible for filming or videotaping the good or bad footage), date, location, and camera serial number (fig. 13-16). If you are part of a large organization that has several crews, then also include the unit number. In short, the slate should contain information needed for proper identification of each scene on your film.

The slate may actually be a piece of slate with the data written or lettered on it in white chalk. Quite often the "slate" is white with an acetate surface, and the data is written on it with a black grease pencil. When you slate a scene, hold the slate in front of the camera lens and record it for about 10 seconds for videotape or 3 feet for motion-picture film.

Of the information you place on your slate should be clearly printed in large, block letters. Film your slate so it fills the complete frame. If your slate is not full frame, the lettering may be too small to read when the tape is viewed.

[illegible]

Figure 13-17.—Video/Film Data Sheet.

If you do not have time to film the slate at the beginning of the scene, do it at the end of the scene. This is known as tail slating. Record the slate upside down, then rotate it right side up when tail slating. This shows that a tail slate was used; otherwise, the viewer might assume that it is associated with the scene following it

on the tape. When recording without a script, you have no scene numbers to slate for each scene; therefore, for identification purposes, you slate only at the beginning of each tape. If for some reason you cannot slate at the beginning, tail slating applies.

Although you, the camera operator, do not derive any particular value from the slate, the person editing your film becomes frustrated, if not completely lost, when slates are not included. This is particularly true when your scenes are not shot in the same order as the script is written. The task of locating individual shots is almost impossible unless each scene is slated when it is originally filmed. You can understand now why you must slate each scene when shooting from a script.

VIDEO/FILM DATA SHEET

Video/film data sheets are valuable to you (fig. 13-17). By looking at them you can tell the scenes that have been shot and those that still need to be done. Their main value, however, is to the editor. Without data sheets, the editor does not know the order in which the scenes were shot. Notice how the slate and data sheets work hand in hand. For a large project, the editor can check the data sheets and find a particular tape or scene easily. By screening just one videotape, the editor can spot the scene by checking the slate images. Imagine looking for a particular scene, at random, when it could be anywhere in a dozen or more tapes. Many hours are wasted when your data sheets are not properly prepared. The data sheet also may prevent accidental use of the wrong footage. If a scene was refilmed to correct an error, both the rejected and corrected versions of the same scene can be identified.

VISUAL INFORMATION CAPTION SHEETS

A Visual Information Caption Sheet, DD Form 2537, must accompany all products forwarded to a Still and Motion Media Records Center. The use of a visual information caption sheet ensures that all necessary caption information is available and standardized so it can be entered into computer data bases at the records center.

The instructions necessary to complete DD Form 2537 are printed on the back of the form. Because the completed form provides the cover story for the motion video product, it is important for you to provide accurate

information and as much detail as possible about the recorded event (fig. 13-18).

VIDEOTAPE CARE

The performance of videotape is often directly related to the care and proper maintenance it has or has

not received. Temperature extremes should be avoided when storing tape between recording and playback. Wide temperature variations can result in a tremendous amount of stress on the innermost tape layers caused by dimensional changes. If a tape has been in storage at sub-zero temperatures, for example, you must

18. EXTENSIVE DESCRIPTION OF PHOTOGRAPHY OR SCENES: (If not applicable, enter "N/A")	
19. COPYRIGHT OR OTHER RIGHTS IDENTIFICATION (if applicable)	
INSTRUCTIONS:	
Items not listed are self-explanatory. ITEM 2. Enter the location where the photograph(s) film or video depicted on this caption sheet were taken. 5. Enter the organization which requested the imagery. 6. Describe media being forwarded to U.S. Records Center by entering an "X" in the appropriate box or boxes. If 6 is marked, explain in item 19. 7. Describe media in which imagery was or is to be recorded. 8. Enter specific film size, e.g. 16mm, 35mm, 405, etc. 9. Enter specific film type, e.g. Kodachrome 64, Ektachrome 200, etc. 10. Specify whether 1" 3-1/4" 8mm Betacam, Mini, 8mm, etc. 11. Specify 1/4" SECAM, NTSC, etc.	ITEM 12. Indicate any film imagery, and specific type such as copy negative, duplicate negative, etc. 13. This is the cover story. Give a complete description of the project, exercise, activity, or event being recorded. Provide as much detail as possible. 14. Provide the unit designation and its home location. 15. Describe the major equipment items or weapon system shown. For example, if there is a photograph of a dog tag, enter "A-150, flying over the Gulf of Mexico, enter "A-150 aircraft and "A-150 tank" in this item. 16. Include the full name, rank, and position of each person pictured, unless all of the above information is not used. Enter the name of the person and his or her position in the photograph.
24. FOR USE BY RECORDS CENTER: a. RECORDS CENTER USE ONLY: (If not applicable, enter "N/A") b. RECORDS CENTER USE ONLY: (If not applicable, enter "N/A")	

DD Form 2537 Reverse, MAR 89

Figure 13-18B.—Visual information caption sheet (back).

“condition” it to room temperature. Complete dimensional equilibrium may take as much as about 16 hours. Never use direct heat to speed up the conditioning process. High temperatures can create harmful differences in layer-to-layer tension on the reel. Never use extreme cold, such as a freezer, to cool down a hot

tape. In general, recommended storage conditions for videotapes are as follows:

Relative Humidity 50% - 60%

Temperature 60°F - 80°F

For best long-term storage, rewind video cassettes uniformly for even tension before boxing. Tapes should always be in one of two places-in the VTR or in the original box. Stand videotape boxes upright. Do not store tapes in a horizontal position. This can cause bending and distorting of reel flanges that can be a major cause of tape edge damage.

To prevent damage, you should protect videotapes by covering them when they are not in use. Keeping them in dustproof cassette containers prevents the accumulation of airborne dust on the tapes. Dust can be a prime cause of dropout. Body oils and salts from your fingertips can pick up and hold foreign particles that, when transferred to the tape, cause dropouts.

CHAPTER 14

JOB CONTROL AND PHOTOGRAPHIC FINISHING

No job is finished until the paper work is complete. This statement holds true for all photographic jobs completed in your imaging facility. In order for your imaging facility to operate efficiently, you must follow the procedures that regulate job control and other administrative procedures within your facility. This chapter is intended as an introduction only. A more in-depth understanding of Navy imaging administrative procedures are found in *the Navy Visual Information Management and Operations Manual*, OPNAVINST 5290.1 (series).

The first topic discussed in this chapter is the handling of classified material. You must learn to follow strict guidelines when handling classified material. There is no allowance for mistakes. Become thoroughly familiar with the standard operating procedures established in your imaging facility.

SAFEGUARDING CLASSIFIED MATERIAL

Modern methods of conducting war and safeguarding our nation require a tremendous amount of information. This information is stored in books and files, it accumulates in reports, it is gathered by intelligence activities, and it is transferred in the form of letters, messages, photographs, and audio and video recordings. This information is sifted and organized in the minds of the people directing the war effort and those keeping the peace. Much of this information is extremely valuable to our enemies, and, therefore, must be classified and safeguarded in the interest of national security.

In performing your job as a Navy Photographer's Mate, you may have access to classified information. Therefore, you **MUST** become aware of the importance of safeguarding all classified information to which you have access.

Classification categories, procedures, and related-security information pertaining to the Navy are contained in the *Department of the Navy Information and Security Program Regulation*, OPNAVINST 5510.1 (series). A copy of this regulation is available in every

Navy imaging facility where classified information is maintained or handled. Refer to this regulation frequently to make sure you safeguard properly classified material. Never depend on your memory regarding the proper disposition of classified information, particularly if you handle it infrequently.

The purpose of the security program is to protect classified material from unauthorized disclosure. It is the responsibility of all military personnel to safeguard classified information.

The Navy controls the dissemination of classified information. Therefore, knowledge or possession of classified information is permitted only to those persons who actually require it in the performance of their duties. This principle is referred to as the "need to know" and is a prerequisite for access to classified information. Access to classified material is not automatically granted because a person has the proper clearance, holds a particular billet, or is sufficiently senior in authority. Access is granted only if the criteria of proper clearance and "need to know" are both met.

Official material that requires protection in the interest of national defense is categorized in three designations. These three designations, in descending order of importance, are Top Secret, Secret, and Confidential. No other designation is used to classify defense matters that require protection in the interest of national defense.

TOP SECRET

The classification "Top Secret" is limited to defense information or material that requires the highest degree of protection. The Top Secret classification is applied only to information or material that is paramount to national security and the unauthorized disclosure of which could reasonably be expected to cause exceptionally grave damage to the national security.

SECRET

Material classified as "Secret" is limited to defense information or material. The unauthorized disclosure of

which could reasonably be expected to cause serious damage to the national security.

CONFIDENTIAL

Use of the classification “Confidential” is limited to national defense information or material, the unauthorized disclosure of which could reasonably be expected to cause damage to national security.

RESTRICTED DATA

The term *Restricted Data* as defined in the Atomic Energy Act of 1954 means all data concerning (1) the design, manufacture, or utilization of atomic weapons; (2) the production of special nuclear material; or (3) the use of special nuclear material in the production of energy.

The term *Formerly Restricted Data* applies to classified defense information which (a) has been removed from the Restricted Data category in order to conform with the Atomic Energy Act of 1954 and (b) cannot be released to foreign nationals except under specific international agreements.

Restricted Data and Formerly Restricted Data are NOT in themselves classification categories, but are additional warning notices of special handling requirements. Thus a classification category is used with the warning notice wherever it is appropriate.

FOR OFFICIAL USE ONLY

The designation “For Official Use Only” is assigned to official information that requires protection according to statutory requirements or in the public interest, but does not require safeguarding in the interest of national defense.

A security classification may not be used to conceal violations of law, inefficiency, or administrative error; to prevent embarrassment to a person, organization, or agency; or to restrain competition.

AUTHORITY TO CLASSIFY

The authority to assign a security classification is restricted to those officials who have been designated the authority in writing.

Original Classification

One important aspect of classification that is commonly misunderstood is the difference between original and derivative classification. Original classification is warranted only when information requiring classification is generated and classification cannot be derived from information that was classified previously. For example, information pertaining to a technological breakthrough or a significant scientific advance generally requires original classification authority.

Derivative Classification

The majority of classified material you work with is the product of derivative classification. As the word implies, this type of classification is based on and obtained from a previous classification. Derivative classification is applied when the information presented is the same (or closely related to) as other information that already is assigned a classification.

Suppose you are making photographs for a report of Iraqi warships in the South China Sea. If the report is based on a source document that states that such photographs should be classified, your classification is derived from that source. Or suppose you take pictures of a radar system that is classified Secret. Then the picture, the negatives, the test prints, and the enlargements are also classified Secret. The classification of the pictures is derived from the classification of the radar system. Most of the information classified derivatively is taken from documents classified previously. Whenever you copy or extract classified information, you must ensure that the extracted information bears the same classification in the new document (such as a photograph) as it did in the source document.

In marking a derivatively classified document, you must cite the source of that classification or authority (e.g., CNO ltr, ser OP-009 of 1 Oct 93) on the “classified by” line. Records must be available for the lifetime of the document to show the basis for classification or to trace the chain of classification authority.

CLASSIFICATION MARKINGS ON IMAGING PRODUCTS

The requester of imaging products determines the security classification of the product according to the guidelines contained in OPNAVINST 5510.1. Each original and all photographic copies that are classified must be marked with the appropriate security classification, the classification authority, and declassification and downgrading instructions based on the original classification markings.

Photographic film, prints, and slides that are classified must be marked with the appropriate classification and other applicable markings.

Film

Roll negatives are marked on the base side with the classification and associated markings at the beginning and end of each strip. Single negatives cut from the roll or single-sheet film negatives must also be appropriately marked on the base side. These materials must be kept in envelopes or film canisters with conspicuous markings.

Transparencies and Slides

The classification and associated markings must be shown clearly on the slide mount or transparency frame and whenever possible on the image area. Because the classification on 35mm slides are not conspicuous until they are projected, the classification must be marked on the slide mount. It is not necessary for each transparency of a set of transparencies to bear applicable associated markings when the set is controlled as a single document. In such cases, the first transparency bears the applicable associated markings.

A camera that contains exposed film of a classified subject must be given the same protection as the classified subject. Be cautious with Polaroid film when photographing classified material. All waste products produced by these films must be destroyed as classified waste.

Prints

All 8x10 and larger prints must be marked with the classification at the top and bottom of the face side with the associated markings at the bottom. On smaller prints the classification is required to appear only once on the face side. When it is not practical to place the classification and associated markings on the face side

of prints, the markings can be placed on the reverse side, using a pressure tape label or a stapled strip when stamping is not practical. All photographic reproductions must show the classification and associated markings clearly.

Motion-Media Products

The beginning of each reel of film or videotape must be marked with a title that bears the classification and associated markings. These markings must be visible when projected on the screen or played through a monitor. Only the overall classification is required at the end of the reel or videotape. Reels and cassettes must be marked with the appropriate classification and kept in containers that are marked conspicuously with the classification and associated markings.

DISCLOSURE OF CLASSIFIED MATERIAL

When classified matter is entrusted or made known to you, you must protect it against loss or compromise. You are responsible for any act or failure that contributes to the loss, compromise, or unauthorized disclosure of classified information. This includes information that is passed verbally.

When you are found responsible for the loss, compromise, or unauthorized disclosure of classified matter or when you violate security regulations, you can expect to be disciplined promptly. Disciplinary action may include, in the case of military personnel, trial by court-martial or, in the case of civilians, prosecution under Title 18, United States Code, as amended, or other federal statutes, as appropriate.

PROTECTIVE MEASURES

Generally, there are four ways that classified information is protected: censorship, physical security, transmission security, and cryptographic security. As a photographer, you will be concerned primarily with personal censorship and physical security.

Personal Censorship

Censorship places a barrier between classified information and unauthorized personnel by preventing disclosure in the form of letters, conversations, and personal contacts. Restricting information at the source, except for official use, depends on the integrity and discretion of the individual.

Physical security

Physical security is the safeguarding of documents, photographs, and other items that contain classified information. Later in this chapter, another form of physical security used to safeguard property and material physically at Navy shore activities is discussed.

Physical security is the concern for protecting classified documents, devices, and materials, so they never fall into the hands of unauthorized personnel or come within optical range of actual or possible enemies. When working with classified matter, you must protect it from being seen by unauthorized individuals, either military or civilian. No person should have access to classified material unless it is necessary for them to carry out their official duties. Classified material must never be removed from its designated working space or left unguarded. When not actually in use, you must keep it locked up in an authorized container.

DESTRUCTION OF CLASSIFIED MATERIALS

When classified products, such as photographs, videotapes, or audio recordings, are no longer needed or useful, they must be destroyed. The products must never be discarded in ordinary containers.

Destruction of classified material must be accomplished and witnessed by persons who are cleared to the level of the material being destroyed. A record of destruction is mandatory even when an originator states in a document that it “may be destroyed without report.” This statement means only that the originator does not need to be notified of the destruction.

A record of destruction is required for Top Secret and Secret material, but not for Confidential material. Destruction may be recorded on OPNAV 5511/12 (Classified Material Destruction Report) or on any other record that includes complete identification of the material, number of copies destroyed, and the date of destruction. The record of destruction must be signed by the two cleared people involved in the destruction of Top Secret materials, and the record must be retained for 2 years.

Classified documents can be destroyed by burning, pulping, pulverizing, or shredding. When destruction is accomplished by means other than shredding, the residue must be inspected to ensure complete mutilation.

In most imaging facilities, the policy is to give all scrap materials, test prints, and any other material

generated from a classified job, back to the requester. Do not destroy classified materials without first consulting your supervisor.

SECURITY AREAS

Spaces that contain classified matter are known as security (sensitive) areas. The areas have varying degrees of security, depending on their purpose, the nature of the work, and the information and materials involved. All security areas should be clearly marked by signs marked Restricted Area. Three types of security areas are established to meet different levels of security sensitivity.

Exclusion Area

Spaces requiring the strictest control of access are designated exclusion areas. They contain classified matter that restrict admittance to only those persons that require access to the materials and have a “need to know.”

An exclusion area is fully enclosed by a perimeter barrier. All entrances and exits are guarded, and only those persons whose duties require access and have the appropriate security clearance are authorized to enter.

Limited Area

A limited area is one where the uncontrolled movement of personnel permits access to classified information. Within the area, access may be prevented by escort and other internal controls.

The limited area is enclosed by a clearly defined perimeter barrier. Entrances and exits are guarded or controlled by attendants to check personal identification. These areas also may be protected by an automatic alarm.

Most Navy imaging facilities should be considered at least a limited area when classified work is in progress. All visitors must be escorted within these spaces. When classified work is in progress, it should be excluded from all personnel who do not have the need to know. Even when classified work is not in progress, it is wise to operate within your imaging facility as though it was a limited area because there is a considerable amount of expensive equipment throughout.

Controlled Area

A controlled area usually does not contain classified information. It serves as a buffer zone to provide greater administrative control, safety, and protection for the limited or exclusion areas. These areas require personnel identification and control systems to limit admittance to those people having bona fide need for access to the area.

Passageways or spaces surrounding or adjacent to limited or exclusion areas may be designated as controlled areas.

SAFEKEEPING AND STORAGE OF CLASSIFIED MATERIAL

Classified information or material must be stored under conditions that prevent unauthorized persons from gaining access to it. The security requirements must allow work to be accomplished while providing adequate security. In the Navy, the commanding officer is directly responsible for safeguarding all classified information within his command. He is also responsible to ensure that classified material is stored properly when not actually in use.

Storage

Whenever classified material is not under the personal control and observation of an authorized person, it must be guarded or stored in a locked security container.

Top Secret material is stored in a safe or safe type of steel file container having a three-position combination lock as approved by the General Services Administration (GSA) or a class A vault that meets the standards established by the Director of Naval Intelligence. An alarm-protected area may be used to protect Top Secret material when the responsible local official decides that an alarm system provides protection equal to, or better than, the safe, steel file, or vault. The alarm-protected area provides a physical barrier that prevents removal of the material and prevents the material from being viewed by unauthorized personnel and compromised.

Secret and Confidential material may be stored in the same manner authorized for Top Secret or, in a class B vault, a vault type of room, or a secure storage room that has been approved according to the standards prescribed by the Director of Naval Intelligence.

Valuables, such as money, jewels, precious metals, narcotics, and so forth, should not be held in safes used to store classified materials because they increase the risk of theft. Only classified materials are to be placed in containers designated for storage of classified material.

Container Designations and Combinations

Containers used for the storage of classified material are assigned a number or symbol for identification purposes. The identifying numbers or symbols are located in an obvious location on the outside of the container. Each container must also meet the security requirements for the highest classification of material stored in the container. However, this designation is not marked externally on the container.

Records of combinations are sealed in envelopes (OPNAV 5511/2) and kept by the security manager, duty officer, communications officer, or other person(s) designated by the commanding officer. Combinations for containers with noncryptographic material will be changed under any of the following conditions:

- When a safe is first placed into use
- Annually
- When the combination or record of combinations has been compromised or a security container is discovered unlocked and unattended
- Whenever an individual knowing the combination is transferred or discharged, or when the security clearance of an individual knowing the combination is reduced, suspended, or revoked

When you are selecting new combination numbers, multiples of 5, simple ascending or descending numerical series, and personal data (such as birthdays and serial numbers) must not be used. The same combination cannot be used for more than one container.

Combinations to security containers are changed only by persons that are cleared for the highest level of classified material stored in the container.

When a security container is taken out of service, built-in combination locks must be reset to the standard combination 50-25-50. Combination padlocks must be reset to 10-20-30.

desk receiving the job request. OPNAV 5216/10 should be unclassified and contain only the information required to identify the material being received. No classified information should be included on a receipt. The postcard receipt (back of OPNAV 5216/10 package) is given to the person delivering the job request. The postcard receipt is then presented to the front desk person when the completed job request is picked up. OPNAV 5216/10 receipts are retained for a minimum period of 2 years.

Whenever you have questions about classified information or security matters, refer to the *Department of the Navy Information Security Program Regulation*, OPNAVINST 5510.1, or the security manager of your command.

VISITOR CONTROL

Physical security is part of an overall Navy program that deals with physical measures designed to prevent unauthorized access to equipment, facilities, and materials.

Navy imaging facilities are a part of this physical security program. Physical security of imaging facilities is a direct, immediate, legal, and moral responsibility of every Photographer's Mate assigned to the activity.

As stated earlier, Navy imaging facilities are considered limited access areas. The reception or job order desk area is the only place within the facility that unescorted personnel, other than personnel assigned to the activity, or visitors are permitted. Beyond the reception area, there must be a definite, well-defined limiting barrier. This barrier may be in the form of a warning sign, locked gate, or a door, depending on the degree of security required.

Procedures for the control of people entering the restricted areas of an imaging facility beyond the barrier include, as a minimum, an escort system. Escorting is a method for controlling personnel within the lab who are not normally authorized access. Whether or not the escort remains with the visitor during the entire time of the visit is determined by the amount of security required, by the purpose of the visit, and by local written policy. Utility and maintenance personnel performing work at regular or irregular intervals and for short working periods should be handled by the same procedures as those used for the control of visitors.

People are curious and like to look at pictures. When unescorted they will probably look through the pictures and negatives in the finishing area. Even if they do not

take the pictures, they most probably will not place them in the same order and the finishing crew will have to re-sort the jobs.

Even when your imaging facility does not handle classified work, you must become aware of the need for security. You must be accustomed to escorting visitors. By escorting visitors, you will find that the disappearance or misplacement of equipment and materials is minimized.

JOB CONTROL

The *Navy Visual Information Management and Operations Manual*, OPNAVINST 5290.1 (series), governs the administration and operation of Navy imaging facilities. It outlines the organization and administration of audiovisual units and provides policies and instructions for the use of imaging products in the Navy. You should consult this manual for the most current information concerning the organization of naval imaging.

The ability to track photographic jobs within your facility quickly and accurately depends on the job control system of your imaging facility. When the system is not used correctly, photographic requests, negatives, prints, and other requirements may be lost or misplaced. This causes an inordinate delay in customer service that has a negative impact on your relationship with other divisions.

JOB-ORDER LOG

An unclassified job-order log is maintained by all imaging facilities. The log must contain, as a minimum, the following information: sequential job order numbers, security classification, product identification, and disposition of the work request (person who picked up the job). Additional data required by your imaging facility, such as date and requester, may also be included in the job-order log.

Unclassified identifiers are used to refer to classified subjects. A separate job-order log is maintained for classified work requests. Job order logs are created on the first day of each fiscal year, and the job order number is reset to 000001. The **fiscal year** of the federal government runs from 1 October to 30 September.

Figure 14-2A.—OPNAV 5290/1 (Front).

VISUAL INFORMATION JOB-ORDER FORM

ALL work performed by Navy imaging facilities must be documented on a job-order form. The job-order form is used to maintain close control of in phases of imaging services. The job-order form serves several purposes; they are as follows: as an official request for visual information (VI) services, as the authority to perform the work, as a record of the time and materials used to complete the job, and as a receipt for the finished work. Navy imaging facilities may use the Request for Audiovisual Services, OPNAV 5290/1 (fig. 14-2A), or a locally created, in-house job-order form.

As a minimum, an in-house job-order form must contain the following information: a job-order number, a customer signature block with a disclaimer that the service requested is official work and essential to mission accomplishment, product security classification, and any other information required by your facility to accomplish the request officially.

Figure 14-2A is an example of an Request for Audiovisual Services, OPNAV 5290/1. Figure 14-2A shows the front side of the form. The front side can be broken down into two sections. The top section, Blocks 1 through 14, may be completed by the requester or a person assigned to the job-control desk by the imaging facility. The completion of these blocks is self-explanatory. Block 2 (the work request number) is the

VISUAL INFORMATION CAPTION SHEETS

A Visual Information Caption Sheet, DD Form 2537, must accompany each product forwarded to a Navy still and motion-media records center. (See fig. 13-18.) The use of the visual information caption sheet ensures that all necessary caption information is available and standardized, so it can be entered into the computer data base at the records center.

The instructions necessary to complete DD Form 2537 are printed on the back of the form. Because the completed form provides the cover story images being forwarded, you must provide accurate information and as much detail as possible about the recorded event.

PHOTOGRAPHIC FINISHING

Photographic finishing is just as important as all the other steps in the photographic process. Normally, the final checks for accuracy and quality are performed in the finishing area.

QUALITY ASSURANCE

When the prints are dry and the job order is completed, you must examine them for defects or other poor qualities such as stains, dust spots, fingerprints, and uneven borders. Many times the prints are on long rolls and must be cut and trimmed into individual prints. After the prints are trimmed, you must sort the prints into groups according to the negatives and job orders. At this stage you can ensure there are enough good-quality prints to fulfill the job order. The following checks must also be made: the correct negatives were printed, the correct size was printed, and the negatives were printed on the correct finish (glossy or matt) paper. Negatives that required additional prints or reprints should be sent back to the print room to correct discrepancies. You are responsible for ensuring that only the highest-quality product leaves the imaging facility.

Rejected prints from classified negatives must be disposed of according to the instructions provided in the *Department of the Navy Information and Personnel Security Program Regulation*, OPNAVINST 5510.1 (series). Rejected prints from negatives that are unclassified must be disposed of according to local instructions.

NOTE: It is the policy of most Navy imaging facilities to return all film and paper scraps, test prints, rejected prints, and so forth, from classified jobs to the

requester. Be sure to follow the policy established locally by your imaging facility.

Do not neglect to check the completion and accuracy of the job order. Be sure that all personnel responsible for completing the job have completed the appropriate blocks. Materials expended for the job, man-hours, and accountability must be provided on the job order. Remember, without this information, proper budgeting and personnel management within your facility cannot be performed accurately.

MARKING VISUAL INFORMATION PRODUCTS FOR FILING

When the negatives and prints are not returned to the requester, they must be marked and captioned before placing them into the local file or forwarding them to a Navy still and motion-media records center. Classified prints must be marked with the appropriate classification as specified in OPNAVINST 5510.1 (series). Refer to chapter 6 for caption writing requirements if you need to refresh your memory.

The guidelines and procedures for marking visual information (VI) products are in chapter 2 of the *Navy Visual Information Management and Operations Manual*, OPNAVINST 5290.1 (series). You should refer to this instruction for the most current information on marking and identifying imaging products.

Each original product retained in your imaging facility file must be identified and recorded in the Visual Information Record Identification Number (VIRIN) log. The following information must be included in product markings:

- ◆ The Department of Defense Visual Information Authorization Number (DVIAN) code
- The VIRIN code
- The last two digits of the fiscal year (FY) in which the image was exposed or recorded
- The six-digit sequence number
- The security classification (if applicable)

Blank–Unclassified

CO–Confidential

SE – Secret

TS – Top Secret

A complete listing of VIRIN codes is contained in OPNAVINST 5290.1 (series). Some of the more commonly used VIRIN codes are as follows:

OTT—overhead transparency
SCN—still photographic negative, color
SPN—still photographic negative, black and white
SPT—still photographic transparency
VSP—video still
VTC—videotape cassette

Each set of characters in the markings of VI products is separated by a hyphen. An example of a VIRIN is as follows: the first product of FY 93 filed by the Fleet Imaging Command Pacific, San Diego; the subject is classified Secret and was shot by a photographer using a still-video camera. The VIRIN is as follows:

NO108-VSP-93-000001-SE

Each authorized imaging facility is assigned a separate DVIAN code. Each original VI product that is marked and filed by your imaging facility must be recorded in the VIRIN log. The VIRIN-log entries must consist of the VIRIN assigned to each original product, the job-order number, format, subject matter, camera-person or artist's name, and final disposition of the product. Like the job-order log, the six-digit sequence number in the VIRIN log is reset to 000001 the first day of the new fiscal year.

Still Photography

Negatives are marked with the VIRIN on the base side, outside the usable image area with permanent ink. Roll negatives are cut into strips and each strip is assigned a separate VIRIN. Individual frames on the strip are then identified by letters (A, B, C, D, and so on). Frames within the strip that are not intended for filing should not be assigned a letter; however, they must not be crossed out.

Transparencies must be mounted in plastic or cardboard mounts with the VIRIN marked on the mount. For still, electronic floppy disks, mark the outside of them with the VIRIN, using permanent ink.

Prints

Photographic prints are marked on the base side with the same VIRIN assigned to the original negative

or transparency. Prints must also include the date the original photograph was taken and the name and address of the originating activity.

Unclassified photographs that are cleared for public release according to the *Department of the Navy Public Affairs Policy and Regulations Manual*, SECNAVINST 5720.44 (series), must be stamped—"United States Navy Photography. Please credit USN PHOTO."

Classified prints must include the security classification, classification authority, appropriate downgrading and declassification instructions, and be stamped "United States Navy Photography."

Photographic prints of mishaps, accidents (including property damage and personal injury), and other types of evidence that are not releasable under the Freedom of Information Act must be stamped "United States Navy Photography."

Motion Media

Each motion-media roll of film, cassette, or disk must be identified with the same information as still-imaging products. However, the data must be recorded at the beginning of the tape for a minimum of 5 seconds viewing time. The VIRIN should also appear on the outside of the cassette or reel, so the product can be identified without actually viewing it. When possible, the VIRIN should be included on the slate. When the VIRIN is included on the slate, all information is provided in the same frame.

NOTE: Remember that all Navy imaging products forwarded to a visual information records center for pre-accessioning must be accompanied by a Visual Information Caption Sheet, DD Form 2537.

FILING IMAGING PRODUCTS

Images that are stored locally must be protected. Standard, VI file cards are commonly used throughout the Navy to protect and file photographic images. These file cards may be color coded to distinguish classification, subject matter, time frame, and so forth. Standard file cards are made of sturdy paper stock. A print of the image, the VIRIN, and the classification are included on the face side of the file card, and the negative and caption are attached to the back. Downgrading instructions must be included for classified images. All negatives filed or handled must be protected by negative preservers.

Photographic negatives and prints should be carefully stored in a file cabinet so they are protected.

You should avoid storing photographic products in cardboard boxes. To prevent damage, never store photographic negatives and prints in storerooms, quonset huts, bilges and so on, where they may be subject to adverse conditions, such as direct sunlight, UV radiation, water, dampness, high humidity, and high temperatures. Videocassettes, audio tapes, and floppy disks must never come in to contact with a magnetic field. A good general rule is to store file images in climatic conditions under which you would be comfortable.

PRINT MOUNTING

For exhibition and display, prints are mounted or matted on a stiff board. The difference between mounting and matting is the way in which a print is attached to the board. When a print is mounted, it is stuck on the face of a mounting board. When a print is matted, it is attached to the back of the board and the image is placed behind a cut opening. When matted, a print is often taped into place, thus the matt can be temporary. Generally, prints that are framed are matted. In both cases, the board enhances the picture by providing a broad border as well as protecting the edges against damage.

When you are preparing a print for exhibition or display, your goal should always be to show the print to best advantage. Simplicity is the best strategy. Elaborate artwork or fancy lettering can often detract from the photograph.

Generally, prints for display purposes are mounted or matted on special card stock to make them stand out from their surroundings. Card stock used for mounting photographic prints should be free of acid or sulfur that can deteriorate the print quality. Card stock is available in various sizes, colors, textures, and weights. There are no hard-and-fast rules for mounting prints, but the card stock should compliment the print. The mount should be large enough to balance and support the picture, and the texture and color should compliment the overall tone.

The way the print is placed on the mounting board is important. Prints mounted at odd angles or in a corner of the mount unbalance the photograph. The bottom border on most mounts is the widest border of all. Normally, prints are mounted so the top and side border of the mount are equal. To provide balance, you should ensure the bottom border is 25 to 35 percent wider than the top and side borders. There are two types of adhesives for mounting prints: wet and dry.

Wet Method

Liquid adhesives, such as rubber cement and spray-on adhesives, can be used to mount prints. These two adhesives are easy and clean to use. After they dry, the excess adhesive can be removed easily by rubbing it lightly. The drawback to using rubber cement and spray-on adhesives is that they are not permanent. In time the print may loosen and peel off the mount. Rubber cement is an ideal adhesive for temporary mounts used in displays or for copying. Gum arabic, glue, or paste should be avoided whenever possible. These adhesives are known to stain the print or smear out from around the edges of the print. This causes smudges on the mounting board.

Dry Method

A dry print-mounting method that uses a pressure-sensitive adhesive is in common use in the Navy. Pressure-sensitive adhesives come in a variety of sizes in both rolls and sheets. These adhesives form a permanent bond and are easy to use for resin-coated papers. To use these materials, you simply apply the print to the sticky surface of the mounting material. You then peel off the protective backing and apply it to a mounting board. If the print is not aligned correctly, you can remove the print and reapply it. Once the print is correctly in place, you must apply pressure to the print and mounting board. Normally, this is done by running the print and mounting board through a specially designed roller assembly. This assembly applies pressure to the materials being mounted. The pressure-sensitive adhesive material contains tiny beads of adhesive. The pressure breaks these beads and releases the adhesive. Once pressure is applied to the materials being mounted, a permanent bond is formed.

A dry-mount press can also be used to mount photographic prints. With a dry-mounting press, heat is used to fuse a mounting tissue between the print and the mounting surface.

A dry-mount press is designed to provide uniform pressure and heat. Even pressure is an important aspect of good, dry mounting. Adequate pressure helps squeeze out air from between the adhesive, print, and mounting board. You should operate the dry-mount press at the temperature recommended by the manufacturer of the mounting tissue. It is better to use a slightly lower temperature to mount prints than a temperature that is too high. Excessive temperatures may cause damage to the print. When temperatures are too high for RC papers, the resin coating blisters or bubbles.

Porous materials, such as mounting board and rag-stock paper, absorb moisture from the air. This moisture becomes trapped between the layers and causes blisters and bubbles in the finished work. For best results, you should predry the materials before beginning the dry-mounting process. This can be done by heating the mounting board or paper in the mounting press to remove the moisture.

The time required to form a good bond varies when you are using a dry-mounting press. You should mount the prints for a minimum amount of time—the time required to squeeze out air and moisture from the materials and to activate the adhesive. Because different materials have different thicknesses and heat-conducting characteristics, you must experiment to determine what amount of time is required to form a good mount. Whenever possible, you should use scraps of materials that are the same as your finished work to determine the best time and temperature for dry-mounting prints.

The final stage of finishing for some photographs is to frame them. There is an infinite number of colors and materials available for framing photographs. The same principles apply for framing photographs that apply to mounting or matting prints. Keep it simple and choose a frame that compliments the photograph, rather than distract from the picture.

SLIDE MOUNTING

Unlike photographic prints, slides must be put into slide mounts in order to be of any use. The process of mounting slides ranges from a simple pair of scissors to slide-mounting machines, costing tens of thousands of dollars.

Whenever handling slides, you should wear cotton gloves to avoid fingerprints on the image area. If fingerprints do get on the slides, a cotton ball moistened with film cleaner should be used to remove them.

Slides can be mounted in either cardboard or plastic slide mounts. When using cardboard slide mounts, you must heat them so the slide adheres to the mount. Navy imaging facilities use plastic slide mounts. The slides can be placed in plastic slide mounts manually or by machine.

To mount slides manually, you must cut the roll into individual frames. Normally, this is done on a light table so the edges of the frame can be seen clearly. To mount a slide, you simply slide the frame into an open slit on the edge of the slide mount. On one side of the plastic slide mount is the lettering, “THIS SIDE TOWARDS SCREEN.” The lettering appears along the side of the open slit. The slide is mounted properly when the emulsion side of the film faces the lettering, and the slide is straight. No light should pass between the edges of the film edges and the mount.

When projected slides appear correctly on the screen, they are placed in the projector (or slide tray) upside down and backwards, as viewed from the operator’s position. An operator’s dot is often placed on the slide mount to aid in organizing the slides in the tray. When the slide is viewed with the emulsion side towards you and the image is upside down, the operator’s dot is marked on the upper right-hand corner of the slide mount. The slides are placed into the slide tray correctly when the operator’s dot can be seen facing the outside of the tray.

APPENDIX I

GLOSSARY

ABERRATION—A defect in the formation of an optical image; for example, astigmatism, chromatic aberration, curvature of field, and so forth.

ABSOLUTE TEMPERATURE—The temperature measured from absolute zero. Expressed as degrees Kelvin ($^{\circ}\text{K}$) in the Centigrade system where absolute zero is -273°C or in degrees Rankine in the Fahrenheit system where absolute zero is -459°F on the scale.

ACCELERATOR—Chemical constituent of photographic developers that activates the developing agent and swells the gelatin to hasten penetration of the solution. See **SODIUM HYDROXIDE**, **SODIUM CARBONATE**, **SODIUM METABORATE**, and **SODIUM BORATE**.

ACHROMATIC COLORS—Colors perceived as having no hue (white, black, gray, and silver).

ACHROMATISM—The absence of chromatic aberration.

ACID, ACETIC—A colorless liquid of pungent odor used in stop baths and in fixing baths. In concentrated form it attacks the skin and produces painful blisters. A concentrated solution of 99% solidifies at 62°F and forms a mass resembling ice (Glacial Acetic-Acid).

ACID, BORIC (BORACIC ACID) H_3BO_3 —Colorless, odorless, transparent crystals, or a white amorphous powder. Slightly soluble in water and more soluble in glycerine and alcohol. Used in toning and fixing baths.

ACID, SULFURIC, H_2SO_4 —syrupy, odorless liquid, colorless or slightly yellow. Used for preparing a tray-cleaning solution and in fixing and reducing solutions.

ACTION—Movement within a scene being photographed. Also, the picture portion of a motion picture as differentiated from the sound track portion.

ACUTANCE—An objective measure of the ability of a photographic material to show a sharp line of demarcation between contiguous areas receiving low and high exposures. It correlates well with

subjective judgments of picture sharpness. It is the mean of the square of the density gradients times the density scale over a boundary.

ADDITIVE PROCESS—Any color process in which a reproduction is formed by a combination of images each of which supplies color in proportion to the color observed in the original scene. In a typical, three-color additive process, the colors of the images are blue, green, and red. See **SUBTRACTIVE PROCESS**.

AGC—Automatic gain control. Regulates the volume of the audio or video light levels automatically within a camcorder.

AGITATION—The act of moving a photographic film, plate, or paper in a processing bath or moving the bath relative to the photographic material during processing.

AIR BELLS—(1) Air bells are bubbles of air that prevent contact between a processing bath and localized areas on the surface of a photographic material. (ASA) (2) Undeveloped spots on negatives or prints caused by air bubbles, preventing access of developer.

ALKALI—A water soluble compound capable of uniting with and neutralizing acids. The alkalies commonly used for photographic processing baths are sodium hydroxide, potassium hydroxide, sodium carbonate (monohydrate and anhydrous), potassium carbonate, sodium tetraborate, sodium metaborate, and ammonium hydroxide.

AMBIENT SOUND—Background sound or wild sound. Sound that surrounds the scene or location, received by the microphone and recorded onto magnetic tape.

AMMONIUM THIOSULFATE, $(\text{NH}_4)_2\text{S}_2\text{O}_3$ —A white salt freely soluble in water. Used in the preparation of rapid-fixing solutions.

ANALOG—An analog signal that fluctuates exactly like the original stimulus (for example, sweep second-hand clock, phonograph player).

ANGLE OF ACCEPTANCE—The angle that objects must align within to affect the reading of a photoelectric exposure meter.

ANGLE OF FIELD—A property of a lens. The angle subtended by the lines that pass through the center of the lens and locate the diameter of the maximum image area within the specified definition of the lens. Also called angular fields.

ANHYDROUS—Dry, containing no water of crystallization.

ANTICURL BACKING—A transparent, gelatin coating sometimes applied to the opposite side of a photographic film from the emulsion to prevent curling by balancing the forces that tend to curl the film, as it is wet and dried during processing.

ANTIHALATION COATING—A light-absorbing coating applied to the back side of the support of a film or plate, or between the emulsion and the support, to suppress halation (also called antihalation backing). *See* HALATION.

ANTISLUDGE AGENT—A chemical compound added to photographic processing solutions to prevent the formation of sludge. Sodium metaphosphate and boric acid are commonly used for this purpose.

APERTURE—In an optical system, an opening through which light can pass.

APERTURE, CURTAIN—The slit in a focal-plane shutter that permits light to reach the film. The slit size may be either fixed or variable.

ARTIFICIAL LIGHT—Illumination provided by incandescent, fluorescent, or flame sources.

ASPECT RATIO—The ratio of the height to the width of the film or television frame; that is, three units high to four units wide (3:4).

ASTIGMATISM—A lens aberration that causes an off-axis point to be imaged as a pair of lines at right angles to each other and in different focal planes. A lens having astigmatism is unable to image horizontal and vertical lines in the same plane with equal sharpness.

ATMOSPHERIC PERSPECTIVE—Applied to the effect of distance created by atmospheric haze in a photograph. It lightens the tones as the distance increases.

AUDIO TRACK—The area of the videotape that is used for recording audio information.

AUTO IRIS—An automatic control of the lens diaphragm.

AUTOFOCUS—A feature of certain cameras or enlargers by which the image is kept in focus automatically regardless of the degree of reduction or magnification.

AVOIRDUPOIS—The system of weights commonly used in the United States and the British Empire in which the primary unit is the pound (7,000 grains); usually expressed in pounds, ounces, and binary fractions thereof.

BACK LIGHT—Illumination from behind the subject in a direction substantially parallel to a vertical plane through the optical axis of the camera.

BACKGROUND—(1) That part of the landscape which is more distant than the principal object from the camera. (2) A screen, drape, or projected scene used in a photography studio behind the subject.

BACKING PAPER (ROLL FILM)—The protective strip of paper to which the film is attached. Backing paper is usually black on one side and colored on the opposite side. Numerals are usually printed on the colored side in a position where they can be viewed through the camera window. Also called duplex paper. (ASA)

BARN DOOR—Folding wings used in front of studio spotlights to aid in directing the light and to shade portions of the subject from direct illumination.

BASE DENSITY—The density of a film base. No plastic is 100% transparent, so all films have some base density.

BATH—Any chemical solution used in processing photographic materials.

BEAM SPLITTER—An optical system so arranged as to reflect or transmit two or more portions of a light beam along different optical paths.

BELLOWS—The extensible lightproof device that joins the lens board to the film support section of a camera

BLEACH, PHOTOGRAPHIC—(1) To remove an image from a photographic film. Especially to do this by converting a metallic silver image to a halide or other salt that can be removed from the film with hypo. When bleaching is not carried to completion, it is called reducing. (2) Any chemical reagent that can be used for bleaching. (3) Any chemical solution used for bleaching.

BORAX—Sodium tetraborate, $\text{Na}_2\text{B}_4\text{O}_7 \cdot 10\text{H}_2\text{O}$; a mild alkali used as an accelerator in photographic developers, particularly for fine-grain effects.

BRIGHTNESS RANGE—Variation of light intensities from maximum to minimum. Generally refers to a subject to be photographed. For example, a particular subject may have a range of one to four—that is, four times the amount of light is reflected from the brightest highlight as from the least bright portion of the subject.

BULB EXPOSURE—An exposure in which the shutter remains open as long as the shutter release mechanism is depressed.

BURNING IN—In photographic printing, a technique by which selected areas of the image are given extra exposure, and the rest of the image is protected against added exposure.

CABLE RELEASE—A device consisting of a stiff wire encased in an outer flexible covering designed to trip a camera shutter without touching the camera itself. One end is threaded to fit the shutter, and the other has a thumb-operated plunger.

CAMCORDER—A portable video camera with videotape recorder (VTR) and a microphone attached to form a signal unit.

CAMEL-HAIR BRUSH—Term used to define any brush with superfine, soft bristles used for dusting lenses and front surface mirrors.

CAMERA—A lighttight chamber, usually fitted with a lens, through which the image of an object is recorded on a light-sensitive material.

CAMERA, IDENTIFICATION—A type of still-picture camera used primarily for the making of identification photographs.

CAMERA, REFLEX—A camera containing a reflecting mirror within the box, so the image may be focused on a ground glass on top of the camera. A single-lens reflex camera has a device to swing the mirror out of the way during the exposure. A twin-lens reflex camera uses two lenses: one for the viewing image and one for the actual picture-making.

CAMERA, VIEW—A tripod-mounted camera that has incorporated into its construction a long bellows, a rising and falling front, horizontal and vertical swing, lateral shift of front and back, and either a reversible or a rotating back. The view cameras versatility is valuable for the correction of

distortions in architectural, close-up, and illustration photography.

CAPSTAN—An electrically driven roller that rotates and transports the videotape past the recorder heads at a precise and fixed speed.

CASSETTE—A light-trapped metal or plastic container for a length of roll film to enable it to be loaded into a camera in full light.

CCD—Charged-coupled device, also called a chip. A small, solid-state (silicon resin) imaging device used in a video camera instead of camera pickup tubes. Inside the chip, image-sensing elements translate the optical image into a video signal. Chip cameras are insensitive to burn in.

CELL, PHOTOELECTRIC—A device by which light is transformed into electrical energy. Used as the sensitive element in exposure meters and optical sound reproducers and projectors.

CENTIGRADE—A thermometer scale having 100 divisions between the freezing and boiling points of water in universal use for scientific purposes. Also called Celsius after its inventor. Centigrade temperatures may be converted to Fahrenheit temperatures with the following formula:

$$F = 9/5C + 32$$

when F = Fahrenheit temperature and C = Centigrade temperature. (PIA)

CENTIMETER—A unit of length in the metric system which is 0.01 of a meter. According to American standards, 1 inch is equivalent to 2.54 centimeters (cm). (PIA)

CHARACTER GENERATOR—An electronic device to create words or graphics that may be electronically inserted or “keyed” over the video picture.

CHARACTERISTIC CURVE—The curve showing the relationship between exposure and resulting density in a developed photographic image. It is usually plotted as the density against the log exposure in candle-meter-seconds. Called also the “H. and D. curve” and the “sensitometric curve.” The abscissa is sometimes an arbitrary relative exposure.

CHEMICAL FOG—Fog appearing during development of parts of a film not exposed to light. (PIA)

CHROMAKEY—An electronic special effect that combines two video sources into a composite picture, creating the illusion that the two sources are physically together.

CIRCLE OF ILLUMINATION—The total image area of a lens, only part of which is actually used in taking a picture.

CLOSE-UP—A photograph or a motion-picture scene taken at a very close range that shows intimate detail and captures and holds audience interest.

COATING, LENS—A thin, transparent coating applied to the surface of lenses or other optical parts to reduce reflection.

COINCIDENCE—Agreeing as to position. In a coincidence type of range finder, when the two half images of a distant object are in exact juxtaposition, they are said to be “in coincidence.”

COLLIMATED—A beam of light is said to be collimated when all of its rays have been made parallel. See **SPECULAR**.

COLOR BALANCE—The relationship between the three images composing a color negative or positive that provides an accurate (or, more generally, the most pleasing) reproduction of natural colors. (PIA)

COLOR BARS—A color standard used by the television industry for the alignment of cameras and videotape recordings.

COLOR CHART—Target for test photography composed of pigmented areas having colors of high saturation, often accompanied by gray scales, and useful in both color photography and in black-and-white reproduction of colored objects. An assembly of chromatic samples illustrating a scheme of color classification. (PIA)

COLOR COMPENSATING FILTER—A filter used to change the overall color balance of photographic results obtained with color film and to compensate for deficiencies in the quality of the light when printing color films.

COLOR TEMPERATURE—The temperature to which a black body radiator must be raised in order that the light it emits may match a given light source in color; usually expressed in degrees Kelvin (°K).

COLOR TEMPERATURE METER—An instrument for estimating the spectral quality of a light source or the illumination on a scene and expressing the value in terms of color temperature. (PIA)

COLOR TRANSPARENCY—A positive image in natural colors on a transparent support intended for projection or for viewing by transmitted light. (PIA)

COLORBLIND—Applied to photographic layers having only natural silver halide sensitivity to blue, violet, and ultraviolet rays. (PIA)

COMA—An aberration of a lens that causes oblique pencils of light rays from an object point to be imaged as a comet-shaped blur.

COMPONENT—The processing of RGB (red, green, and blue) channels as three separate channels.

COMPOSITE SIGNAL (Y/C)—(Also called NTSC signal.) The video signal in which luminance “Y” (black and white) and chrominance (red, green, and blue) and sync information are encoded into a single signal.

CONJUGATE DISTANCE—The distances of object and image from the lens are called conjugate distances. For every position that an object may occupy with respect to a lens, there is a corresponding position for the image.

CONTACT PRINT—Print produced by exposure in immediate contact with the original or negative. These prints are the same size as the original or negative.

CONTAMINATION—Foreign matter in a processing solution which impairs its operation.

CONTINUOUS TONE—Photographs in which the detail and tone values of the subject are reproduced by an infinite gradation of gray densities between white and black. (PIA)

CONTRAST, LOW—A term expressing a relationship of image tones in which highlights and shadows are represented by very little difference in densities.

CONTRASTY—Photographic term applied to images showing accentuated highlights and shadows. (PIA)

CONTROL TRACK—The area of the videotape used for recording the synchronization information (sync spikes).

COPY—(1) Any document or photograph to be reproduced. (2) The results of such reproduction. (3) (Verb) The act of reproducing a document.

COPYBOARD—The board, frame, or other device for holding copy to be photographed.

CORROSION—The erosion of metals, as by the action of an acid or an alkali; rusting; oxidation. (PIA)

COUPLER—Chemical compound in color developer that can react with the oxidized developing agent in the sensitized material to form a dye color.

CRITICAL FOCUS—That point of focus at which resolution is at its maximum. (NMA)

CROP—To trim or cut off parts of the picture by printing methods to eliminate superfluous portions, and thus improve the composition.

CROP MARKS—Markings placed on original copy, indicating where part of the top, bottom, or sides of the picture are to be omitted.

CURVATURE OF FIELD—An aberration of a lens that causes the image of a plane to be focused into a curved surface instead of into a plane.

CUTAWAYS (MOTION PICTURE)—Shots of related and previously established outside interest used to divert the audience attention in order to cover jumps in action, screen-direction changes, and passage of time.

D-LOG E CURVE—*See* CHARACTERISTIC CURVE.

DARK SLIDE—The opaque slide that covers the film in a film holder, plate holder, film pack, or film magazine.

DARKROOM—A room in which all light of color quality not safe for undeveloped sensitized materials has been excluded. It is used for loading and unloading and the developing of exposed photographic film or paper.

DENSITOMETER—Device to measure the optical density of an image or base by measuring the amount of incident light reflected or transmitted. (NABDC)

DENSITY—The light-absorbing quality of a photographic image is usually expressed as the logarithm of the opacity. Several specific types of density values for a photograph may be expressed; however diffuse transmission density is one of the most important for photographic transparency materials, such as negatives. Diffuse reflection density is generally of interest for photographic prints.

DEPTH—In a nonstereoscopic picture, an illusion of three-dimensional space that is sometimes created by a combination of favorable lighting and coloring of the set and favorable viewing conditions for the reproduction.

DEPTH OF FIELD—The distance between the points nearest and farthest from the camera that are acceptably sharp at a given lens setting.

DEPTH OF FOCUS—The allowable error in lens-to-film distance within which an acceptably sharp image of the subject focused upon will still be obtained.

DEVELOPER (CHEMICAL)—A chemical reagent used to produce a visible image on an exposed photographic layer.

DEVELOPER, COLOR—A photographic developing solution capable of reducing silver halides with the simultaneous production of an insoluble colored oxidation product in the regions where silver is deposited.

DEVELOPING AGENT—Chemicals used in the photographic processing baths to convert the latent image into a visible and photographically useful image.

DIAPHRAGM—A device, such as a perforated plate or an iris, that limits either the aperture of the lens, the field covered by the lens, or both, depending upon its location.

DICHROIC FOG—A deposit of colloidal silver on a photographic film caused by improper processing. This deposit commonly appears red by transmitted light and greenish by reflected light.

DIFFRACTION (OPTICS)—The bending of light waves around the edges of opaque objects.

DIFFUSER—Device for obtaining diffuse direct illumination, such as a wire screen, piece of cloth, or translucent membrane, placed between a light source and the subject illuminated.

DIFFUSION—(1) (Optical) The scattering of light rays so as to cause the light falling on a surface or passing through an aperture to be coming from all directions in contrast to the regular radiation of light from a point source. Diffusion may be introduced by reflection from a matte surface, by transmission through a frosted or opal glass, or by the use of an integrating bar. When diffusion is complete, a sharp image of the light source can no longer be seen, and its place is taken by a uniform, extended source that emits light equally in all directions. (2) (Chemical) The migration of molecules or ions in a solution tending to reduce a difference in concentration between two adjacent regions.

DIGITAL VTR—A videotape recorder that translates and records the analog video signal in digital form.

DIRECT POSITIVE—A positive image obtained directly from another positive image without the use of a negative.

DODGING—A printing technique in which certain areas being exposed are temporarily shielded, thereby producing a different exposure than that used for the rest of the print.

DROPOUT—A loss of part of the video signal that appears as white glitches. Caused by dirty VTR heads or poor quality videotape.

DRY MOUNTING—A method for mounting photographs or artwork on a support by means of a thermosetting laminate that is heated to effect a bond. (PIA)

DRYING MARK—Spots or streaks on negatives and prints differing in density from the surrounding area, produced by uneven drying of the film during processing.

DUB—Duplication of an electronic recording, either tape to tape, record to tape, or vice versa. Dub is always one generation away from the original recording.

EKTACHROME—A trademark of Eastman Kodak Company for a multilayer reversal color film in which couplers are incorporated in the emulsion layers that form dyes in the emulsion during processing.

EKTACOLOR—A trademark of Eastman Kodak Company for a multilayer color negative film in which dye couplers are incorporated in the emulsion layers which upon development produce dye images complimentary to the object colors. Unused couplers remaining in the emulsion after development provide automatic masking for correction.

ELECTROMAGNETIC SPECTRUM—The entire range of wavelengths, extending from the shortest to the longest or conversely, that can be generated physically. This range of electromagnetic wavelengths extends almost from zero to infinity and includes the visible portion of the spectrum known as light.

EMULSION (SILVER HALIDE)—A suspension of light-sensitive silver salt, especially silver chloride or silver bromide, in a colloidal medium, usually gelatin, used for coating photographic film, plates, or papers.

EMULSION SIDE—That side of a (single coated) photographic film on which the emulsion has been coated

EMULSION SPEED—A comparative measure for a given emulsion of exposure to light required to produce a correctly exposed image.

ENLARGEMENT—A print made from a smaller negative through a projection process.

ENLARGER—A photographic projection printer. (PIA)

EXHAUSTION—The state of depletion reached by a processing solution due to age or use that makes it incapable of producing satisfactory results. (PIA)

EXPIRATION DATE—A date placed on sensitized photographic material packaged by the manufacturers to limit the period during which it is warranted to produce normal results.

EXPLODED VIEW—A photograph showing the correct sequence and relationship of the various parts of an assembly. Also called an exploded photograph.

EXPOSURE—(1) The act of exposing a light-sensitive material to a light source. (2) A section of a film for an individual exposure, as a roll containing six exposures. (3) The time during which a sensitive surface is exposed, as an exposure of 2 seconds. (4) The product of light intensity and the time during which it acts on a film, plate, or paper.

EXPOSURE INDEX—An exposure index is the rating of a film for use in connection with exposure tables, exposure computers, and exposure meters.

EXTENSION TUBE—A device used to increase the lens-to-film distance for extreme closeup photography.

FAHRENHEIT—A thermometer scale, on which, under standard atmospheric pressure, the freezing point of water is 32 degrees, and the boiling point of water is 212 degrees; usually indicated as 32°F and 212°F. Fahrenheit temperatures may be converted to Centigrade temperatures with the following formula:

$$C = 5/9 (F - 32)$$

when C = Centigrade temperature and F = Fahrenheit temperature. (PIA)

FAST—Having a high-photographic speed. The term may be applied to a photographic process as a whole, or it may refer to any element in such a

process, such as the optical system, the emulsion, or a developer.

FAST FILM—Photographic material of relatively high sensitivity to light, having a high-exposure index. (PIA)

FIELD—Scanning lines in one half of one video or television frame. There are two fields (one odd, one even) in a frame. One field equals 262.5 scanning lines that create a total of 525 standard television lines or one frame. Also known as the NTSC signal (U.S. T.V. system).

FILM, COLORBLIND—Film which is sensitive only to light of very short wavelengths (ultraviolet, violet, and blue). (NMA)

FILM, PHOTOGRAPHIC, INFRARED—Film coated with an emulsion especially sensitive to infrared light.

FILM, PHOTOGRAPHIC, ORTHOCHROMATIC (ORTHO)—A black-and-white film coated with an emulsion that is sensitive to ultraviolet, violet, blue, and green radiation. Not being sensitive to red, red objects photographed with orthochromatic films are rendered dark on the print.

FILM, PHOTOGRAPHIC, PANCHROMATIC (PAN)—A black-and-white film coated with an emulsion that is sensitive to ultraviolet, violet, blue, green, and red radiation. The special sensitivity of panchromatic films approach that of the human eye.

FILM, PHOTOGRAPHIC, REVERSAL—A film which after exposure is processed to produce a positive image instead of the customary negative image. Reversal films may be black and white or color.

FILTER—Photographic. A layer of glass, gelatin, or other material used to modify the transmitted light selectively.

FILTER, NEUTRAL DENSITY—One not selective for a certain portion of the spectrum but absorbing all colors equally, thus reducing the intensity of light without changing its chromaticity.

FILTER FACTOR—The number of times exposure must be increased to compensate for light absorbed by a filter.

FIXED FOCUS—The term applied to optical instruments and photographic equipment that are not provided with a means for focusing.

FIXER—A solution used to remove undeveloped silver halides from photosensitized emulsions. The fixer usually contains sodium or ammonium thiosulfate, a hardening agent, and an acid or acid salt.

FIXING AGENT—A photographic chemical that dissolves the silver halides not used for producing an image to preserve the photograph from further photographic effect upon subsequent exposure to light. Common fixing agents are sodium thiosulfate and ammonium thiosulfate.

FLARE—A defect of optical systems in which scattered light resulting from reflections at optical surfaces, the walls of the camera, or imperfections in the optical parts, reaches the image plane and produces an overall fog or flare spot that damages the photographic quality of the resulting record.

FLASH, ELECTRONIC—A high-voltage light source for photographic illumination, producing a momentary flash of light of high intensity in an atmosphere of gas enclosed in a tube that can be used repeatedly. (PIA)

FLAT—An image is said to be “flat” if its contrast is too low. Flatness is a defect that does not necessarily affect the entire density scale of a reproduction to the same degree. Thus a picture may be “flat” in the highlight areas or “flat” in the shadow regions, or both.

FLOATING LID—A lid designed to float on the top of a photographic processing solution to reduce aerial oxidation.

FLOODLIGHT—A photographic light used to produce even lighting on large subjects. A floodlight spreads light evenly over a wide angle, as distinguished from a spotlight that concentrates light in a beam.

FLUID OUNCE—A unit of capacity in the Liquid Measure System equal to 1.8 cubic inches; it is equal to 29.57 milliliters.

FOCAL PLANE—The surface (plane) on which an axial image transmitted by a lens is brought to sharpest focus; the surface occupied by the light-sensitive film or plate in the camera.

FOCAL POINT—The point at which converging rays of light from a lens meet.

FOCUS—(1) The point at which rays of light passing through different parts of a lens converge to form a sharp image of the original. (2) (Verb) To adjust the position of either the lens or focusing screen in a

camera or projector to secure the sharpest possible image of the object.

FOG—Nonimage photographic density. The defect is due either to the action of a stray light, to improperly compounded processing solutions, or to wrongly stored or outdated photographic materials.

FOREGROUND (PHOTOGRAPHY)—That part of the landscape imaged in a horizontal or oblique photograph that is closer than the principal object to the camera. (ASP)

FRAME—(1) Any single exposure contained within a continuous sequence of photographs. (2) The smallest unit in television or film—a single picture. A complete scanning cycle of the two fields every 1/30 second. A frame equal to 525 scanning lines.

FREEZE FRAME—Arrested motion that is perceived as a still shot.

FULL APERTURE—The maximum opening of a lens diaphragm. (PIA)

FULL STOP—The standard series of diaphragm markings, or stop openings, that are 0.7, 1.0, 1.4, 2.0, 2.8, 4.0, 5.6, 8, 11, 16, 22, 32, 45, 64, 90, and 128.

FUZZINESS—Lack of image sharpness caused by a defective lens, poor focus, movement, and so forth.

GAIN—The level of amplification for video or audio signals. Increasing the video gain increases the picture contrast.

GENERATION—The number of dubs or copies away from the original recording. The greater number of generations, the greater loss of picture quality.

GRADUATE—A container for liquids marked off to measure various volumes. (PIA)

GRAIN—The discrete particles of image silver in photographs. The random distribution of these particles in an area of uniform exposure gives rise to the appearance known as “graininess.”

GRAININESS—The subjective impression of non-uniformity in an area of a photograph corresponding to uniform exposure, most often noticeable in enlargements with a magnification of 10 or more.

GRANULARITY—An objective quantitative measure of graininess.

GROUND GLASS—A sheet of glass with a grained or matte (translucent) surface, a focusing screen, diffusing screen, and so forth. (PIA)

GUIDE NUMBER—Values assigned to photographic flood and flash lamps according to American Standard to rate their light output in terms useful in exposure calculation. The guide number for a particular lamp used with a particular film is divided by the distance in feet from the lamp to the subject to find the f/number.

HALATION—A halo or ghost image surrounding the true image of a bright object on a photographic emulsion, caused by reflection of rays of light from the back of the negative material.

HALFTONE—Reproduction of a photograph in which the gradation of tone is reproduced by various sized dots and intermittent white spaces caused by interposing a screen between the lens and the film. (IABPAI)

HALIDE—Any compound of chlorine, iodine, bromine, or fluorine, and silver. Silver bromide, silver chloride, and silver iodide are the light-sensitive materials in silver emulsions.

HANGER, FILM—A frame, usually of metal or plastic, for holding one or more photographic films to facilitate handling during processing.

HARDENER—A chemical that increases the melting point of gelatin in photographic layers and prevents softening in warm-processing baths. Hardeners commonly used in photographic processing baths are aluminum potassium sulfate, chromium potassium sulfate, and formaldehyde solution. (PIA)

HAZE—The presence of foreign matter in the atmosphere to an extent sufficient to reduce even slightly its transparency.

HEAD-ON SHOT—A directionless shot in which the subject comes directly toward the camera. Used to change screen direction.

HEADS—A small assembly within an audio or video recording system that can erase, record, or playback the signal in electromagnetic impulses.

HELICAL SCAN, OR HELICAL VTR (ALSO CALLED SLANT TRACK)—A videotape recording or a videotape recorder in which the video signal is put on tape in a slanted, diagonal way. Because the tape wraps around the head drum in a spiral-like configuration, it is called helical.

HIGH-ANGLE SHOT—A scene photographed on a downward angle; the camera being placed above the action.

HIGH CONTRAST—A term expressing a relationship of image tones in which highlights and shadows are represented by extreme differences of density.

HIGH KEY—A term applied to a photographic print or subject consisting entirely of light tones with little contrast; also applied to a method of lighting a subject.

HIGHLIGHT—The bright parts of a picture or subject that are rendered as dense areas in the negative and by very low density in the print.

HUE—That attribute of certain color perceptions in respect to which they differ characteristically from the gray of the same lightness and which permits them to be classed as reddish, yellowish, greenish, or bluish.

HYDROMETER—Generic term for various instruments designed to determine the specific gravity of liquids. (PIA)

HYDROQUINONE $C_6H_4(OH)_2$ —Common photographic developing agent para-dihydroxybenzene.

HYPERFOCAL DISTANCE—The distance from the optical center of lens forward to the nearest plane in acceptable focus when the lens is focused at infinity distance.

ILLUMINANCE—Luminous flux incident per unit area of a surface. Widely known as illumination.

IMAGE, LATENT—The invisible image produced by the action of radiant energy on a photosensitive surface. It may be made visible by the process of photographic development.

IMAGE, NEGATIVE—A photographic image in which the values of light and shade of the original subject are represented in inverse order. In a negative, light objects are represented by high densities and dark objects are represented by low densities.

IMAGE, POSITIVE—A photographic image in which the values of light and shade of the original subject are represented in their natural order. In a positive, light objects are represented by low densities and dark objects are represented by high densities.

IMAGE PLANE—The plane in which the image lies or is formed. It is perpendicular to the axis of the lens. A real image formed by a converging lens would be visible upon a screen placed in this plane.

INCANDESCENT—Glowing with heat, such as the tungsten filament in an incandescent lamp.

INCIDENCE—The act of falling upon or affecting, as light upon a surface.

INFINITY—A distance so far removed from an observer that the rays of light reflected to a lens from a point at that distance may be regarded as parallel. A distance setting on a camera-focusing scale.

INFRARED—Pertaining to or designating those rays which lie just beyond the red end of the visible spectrum. They are invisible and are detected by their thermal, photoelectric, and photographic effects. Their wavelengths are longer than those of light and shorter than those of radio waves.

INTERNEGATIVE—An internegative film is a negative derived directly from a color reversal original film. All other color-duplicating negatives derived from any other than reversal film are known as color-duplicating negatives regardless of the generation.

INVERSE SQUARE LAW—The intensity of light received at a point (irradiance) varies inversely as the square of the distance from the source. The law holds for relatively small sources only and is useful in calculating photographic exposures. (PIA)

IRIS DIAPHRAGM—Term applied to the adjustable aperture fitted into the barrel of the photographic lenses and so-called because of the contraction of the aperture resembles that of the iris (pupil) in the human eye. It consists of a series of thin metal tongues overlapping each other and fastened to a ring on the lens barrel, the aperture made smaller or larger by turning the ring. (PIA)

JOGGING—Frame-by-frame advancement of videotape.

KELVIN (°K)—Measurement of the color of light in degrees. Numerically, the Kelvin temperature is equal to the Centigrade temperature plus 273 degrees.

KEY LIGHT—The main source of illumination on a subject. (PIA)

LAMP, PHOTOFLOOD—A lamp designed to yield brilliant diffuse illumination. These lamps are generally short-lived. (NMA)

LAMP, REFLECTOR FLOOD—Light bulb with self-contained silvered surface to act as a reflector.

LAMP HOUSE—That portion of an enlarger, reader, or projector that contains the light source and condensers or mirror.

LAW OF REFLECTION—The angle of reflection is equal to the angle of incidence.

LENS—In photography, the optical instrument or arrangement of light-refracting elements in a group; the whole designed to collect and distribute rays of light in the formation of an image.

LENS, COMPOUND—A lens composed of two or more separate elements with a common axis. (PIA)

LENS, MIRROR—One employing reflecting elements in addition to light-transmitting elements; usually to obtain compactness in telephoto objectives. (PIA)

LENS ELEMENTS—Individual simple lenses that are combined to form a compound lens. (PIA)

LIGHT, AMBIENT—Surrounding light; the general room illumination or light level.

LIGHT, DIFFUSED—Light that does not reach the subject in a single beam but is scattered by a medium, such as clouds, ground glass, spun glass, or thin fabric.

LIGHT, FILL-IN—Secondary illumination directed to illuminate shadow areas and avoid excess contrast. Also known as fill light. (PIA)

LIGHT, INCIDENT—The light that strikes an object, distinguished from the light reflected from or transmitted by the object. (PIA)

LIGHT, POLARIZED—Light in which the electric vector of the wave vibrates in one plane, rather than all planes, as it does in ordinary (unpolarized) light. Light may become polarized by reflection or by passing through optical devices or sheets known as “polarizers.”

LIGHT BOX—A device for viewing transparencies or negatives, providing diffuse illumination evenly dispersed over the viewing area.

LIGHT SENSITIVE—Materials that undergo changes when exposed to light. The commonly used photographic light-sensitive materials are the silver halides used in films and papers, diazo dyes, and bichromated gelatin. (PIA)

LIGHTING, FLAT—Illumination of a photographic subject often achieved by frontlighting or multiple sources with diffusers that minimizes contrasts and shadows. (PIA)

LIGHTING, FRONT—Illumination on the subject coming from near the camera position. (PIA)

LIGHTING, INDIRECT—Illumination by means of light reflected to the scene from shielded sources.

LIGHTING, LOW KEY—A type of lighting which when applied to a scene results in a picture having gradations from middle gray to black, with comparatively limited areas of light gray and whites.

LINE COPY—A document consisting essentially of two tones (such as black and white, black and tinted, and brown and buff) without intermediate tones.

LITER—A unit of capacity in the metric system, equivalent to 1.056 quarts in United States customary liquid measurement. (PIA)

LOADING—The insertion of photographic film, plates, or paper into holders, hangers, magazines, and so forth, before exposure or processing.

LONG SHOT—In motion pictures, a scene filmed at a considerable distance from the camera to establish locale. Also applied to scenes which show full-length figures, as opposed to waist-length, head and shoulders, and so forth.

LOW-ANGLE (SHOT)—Where camera is placed low and the scene is photographed at an upward angle.

LUX—Lumen per square meter, a unit of illuminance.

MASK—(1) An opaque sheet of thin material used to limit the area of a picture or to secure white margins on a photograph. (2) A supplementary negative or positive used for the purpose of contrast correction in black-and-white prints. (3) A supplementary positive either on a separate sheet or incorporated in an integral color tripack negative for the purpose of color correction. (PIA)

MATTE—A relatively dull surface on photographic prints, having a very low level of specular reflection.

MATTE BOX—A device attached to the front of a camera to hold mattes, filters, diffusing screens, and so forth, in front of the lens.

MEDIUM—Any substances or space through which light can travel.

METER—A unit of length measurement in the metric system approximately equal to 39.37 inches.

METOL-HYDROQUINONE (M-Q)—Designating photographic developers that use a combination of metol and hydroquinone as the developing agent.

METRIC SYSTEM—A decimal system of measurement based on the meter as the unit of length, the kilogram as the unit of mass, and the liter as the unit of capacity.

MICRON—A unit of length in the metric system equal to 0.001 millimeter.

MILLILITER—A unit of volume in the metric system.

1 mL = 0.03381 fl oz

29.57 mL = 1 fl oz

3785 mL = 1 gal

MILLIMETER—A unit of length measuring 0.001 of a meter; 25.4 millimeters equal approximately 1 inch.

MILLIMICRON—A unit of length in the metric system equal to 0.001 micron. It is also equivalent to 10 angstroms.

MODELING—Photographic term for the feeling of “plasticity” engendered by a photograph or the three-dimensional effect produced in a photograph by effective camera work and lighting. (PIA)

MOTTLE—A photographic defect characterized by nonuniform density differences; usually in the pattern of tiny, circular areas.

MOUNT, BAYONET—A means of quickly attaching or removing a lens or filter by turning through only part of a revolution.

MOUNTING—The process of fastening a photographic print to a support.

NEAR POINT—The nearest object to the camera that is still acceptably sharp when the camera is focused for a given distance.

NEGATIVE, BLACK-AND-WHITE—A photographic image on film or paper in which light tones are rendered dark and dark tones appear light.

NEGATIVE, COLOR—A negative record of the color values of the original object. Not only are light values represented by negative densities but colors are represented negatively by their color complements. (PIA)

NEUTRAL—Hueless or achromatic color; gray. Chemically, a solution that is neither acid nor alkaline. (PIA)

NOISE—Unwanted sounds or electrical interference in an audio or video signal. In the audio track, there is a hiss or humming sound. In the video picture the interference appears as “snow.”

NORMAL—Sometimes called the perpendicular. An imaginary line forming right angles with a surface or other lines. It is used as a basis for determining angles of incidence, reflection, and refraction.

NOTCHING CODE—One or more notches of characteristic shape placed by the manufacturer in one edge of a sheet of photographic film to identify the emulsion side and the emulsion type. (PIA)

NTSC—National Television Standards Committee. U.S. standards for television or video signal broadcasting. Also known as the composite signal (Y/C).

OPACITY—(1) The ability of an object to absorb light. (2) Photographic term for the light-stopping power of the silver deposit in negative images. Opacity = 100/Transmittance in percent.

OPAQUING—All handwork on a negative to remove spots or unwanted images.

OPEN FLASH—A method of taking photoflash pictures in which the camera shutter is held open during the flash and then closed.

OPTICAL CENTER—The point, generally within a lens but sometimes exterior to it, at which the optical axis and all chief rays of oblique ray bundles intersect.

ORIGINAL—Material from which copies are made, such as handwritten copy, typed copy, printed matter, tracings, drawings, and photographs. (IABPAI)

OVERCOATING—A thin layer of clear or dyed gelatin sometimes applied on top of the emulsion surface of a film to act as a filter layer or to protect the emulsion from abrasion during exposure and processing.

OVERDEVELOP—To permit a photographic image to be developed too much because of one or more of the following factors: (1) excessive time, (2) excessive temperature, (3) overstrength of developer solution, and (4) excessive agitation.

OVEREXPOSE—To permit too much exposure of a photographic emulsion. This may be caused by (1) too brilliant light, (2) too large an aperture, or (3) too much time.

OVEREXPOSURE—A photographic exposure that exceeds the maximum latitude of the sensitized materials.

OXIDATION—Chemical combination of oxygen with other substances. In photography, the loss of activity of developer solutions is due partly to oxidation of the developing agent with oxygen in the air and partly to oxidation with the silver halide during development. (PIA)

PAN (WITH A CAMERA)—During the course of photographing a scene, to swing the camera around in such a way as to follow the action. Derived from: Panorama. Camera pans are commonly described as slow-pan, fast-pan, swish-pan, and jerky-pan.

PAPER, VARIABLE CONTRAST—Photographic paper coated with emulsions having contrast characteristics grading from soft to hard, depending on the color of the exposing light as modified by a series of filters supplied for that purpose.

PARALLAX—The apparent displacement of an object seen from different points. Commonly encountered in photography in the difference between the image seen in the viewfinder and that actually taken by the lens.

PERSISTENCE OF VISION—A property of the eye that consists of an inability to detect the flickering of a light that exceeds a certain critical frequency.

PERSPECTIVE—The relative size and alignment of objects as recorded on a plane surface; the illusion of three dimensions created on a flat surface.

PHOTOELECTRIC CELL—A cell that converts light energy proportionally into electrical energy. It is used in exposure meters and sound recorders and reproducers.

PHOTOMETER—An instrument for measuring the visual intensity of light, specifically for comparing the relative intensities of light emitted from different sources of illumination. (PIA)

PICKUP TUBE—The imaging device of a video camera that converts light into electrical energy—the video signal.

PINHOLE—(1) Term applied to tiny spots in a photographic negative; usually produced as the shadow of a dust particle during exposure, more rarely the result of chemical dust contamination or gas bubble formation in the gelatin layer due to improper processing. (2) Tiny or white or clear areas in a print or drawing material.

PINT, LIQUID—A unit of capacity equal to 16 fluid ounces, or 473.17 milliliters.

PIXEL—The smallest single picture element with which an image is constructed. The light-sensitive elements in a CCD (chip) camera.

PLANE—A surface which has no curvature; a perfectly flat surface.

POLARIZER—An optical device for converting unpolarized, or natural light, into polarized light.

POSITIVE, BLACK AND WHITE—A photographic image on film, plate, or paper in which light tones appear light and dark tones are rendered dark

POSITIVE FILM—Photographic film, designed for the printing of positive transparencies from negatives.

POSITIVE PRINT—A print in which the light and dark areas as they exist in the original.

POTASSIUM BROMIDE (BROMIDE OR POTASH), KBr—White crystals, very soluble in water. Used as a restrainer in developing solutions. Also used in bleaches and clearing solutions.

POTASSIUM HYDROXIDE KOH—Caustic alkali used as an accelerator in photographic developers. Concentrated solutions are quite caustic and will attack the skin, causing painful burns. Similar to sodium hydroxide.

POWER, RESOLVING—The measure of the ability of a lens, a photographic material, or a combination of both, to distinguish detail under certain specific conditions, among which are the shape and contrast of the target, the quantity of illumination, the exposure and the method of processing. The measure of this ability is expressed in lines per millimeter or in angular resolution of a lens.

PREROLL—To start a videotape and let it roll for a few seconds before it is put in the playback or record mode, so the electronic system has time to stabilize.

PRESERVATIVE—The ingredient of a photographic developer that protects it from rapid oxidation.

PRINTER, CONTACT—A photographic printer in which the negative is held in contact with print material during the exposure. The image of a print made with a contact printer is the same size as the image in the negative.

PRINTER, PROJECTION—A photographic printer in which the negative is positioned some distance from the print material; the image being projected onto the print material. The image of a print made with a projection printer is usually larger than the image in the negative.

RADIANT ENERGY—Energy in the form of an electromagnetic wave; for example, gamma rays, X rays, ultraviolet energy, light, infrared energy, radiant heat, and radio waves.

RADIATION—The process of emitting electromagnetic energy.

RECIPROCITY LAW—Exposure is equal to the intensity of the exposing light multiplied by the time during which it acts. The same density should be produced in a photosensitive material by an equal exposure obtained by doubling the intensity of the light and cutting the time of the exposure in half. This law is only approximately followed by photographic materials, and deviations from it are known as “reciprocity law failures.”

RECTILINEAR—In a straight line. When applied to a lens, it indicates that images of straight lines produced by the lens are not distorted.

REDUCING AGENT—A chemical constituent of a photographic developer that changes the exposed silver halide to metallic silver. Reducing agents must be combined with other chemicals to confine their activity to the silver grains that have been exposed, to control the rate of reaction, and to preserve the agent from combining with oxygen in the air before it can do the work of development. Reducing agents are also called photographic developers.

REFLECTED LIGHT—Light that has been deflected from an opaque surface; not having been absorbed.

RELATIVE APERTURE—The relative aperture is the ratio of equivalent focal length to the diameter of the effective aperture. The symbol for relative aperture written as a fraction is $f/$ followed by a numerical value. To illustrate, the expression $f/2$ signifies that the diameter of the effective aperture is one half of the focal length.

RELATIVE HUMIDITY—Ratio of aqueous vapor present in a space at a given temperature, as compared with the greatest amount it could possibly contain at that temperature.

REPLENISHER—An additional agent used to maintain the chemical strength of a processing solution at a constant level. (NMA)

RESOLUTION—In optics, the ability of a lens system to reproduce an image in its finest details. See RESOLVING POWER.

RESOLVING POWER—The degree to which a lens, optical system, or film emulsion is able to define the details of an image, expressed as the maximum number of black lines, with equal white interspaces per millimeter discernible in the image. Results obtainable for a given lens or emulsion vary with contrast of the original image and with development.

RESTRAINER—The ingredient of a photographic developer that prevents too rapid development and that minimizes chemical fog.

RETICULATION—A processing defect affecting gelatin layers on a photographic film which, upon drying, shows an irregular surface due to the formation of small, irregular scaly patterns. Sharp differences in the temperatures of successive processing solutions and insufficient hardening of the gelatin are the usual causes of reticulation.

RGB—The separate red, green, and blue color (chrominance), or “C”, video signals.

SCALE, FOCUSING—A calibrated scale that permits focusing a camera without the use of a range finder or ground glass.

SCRIM—Diffusing medium placed in front of lamps.

SEMIMATTE—A surface having a moderate, interrupted sheen midway between glossy and dull, or full matte.

SENSITIVITY—The degree to which an emulsion reacts by the formation of a latent image under given exposure conditions, especially as this relates to exposure by different wavelengths (colors) of light. (NMA)

SENSITIZING DYE—Any dyestuff used for sensitizing a photographic emulsion.

SENSITOMETER—An instrument with which a photographic emulsion is given a graduated series of exposures to light of controlled spectral quality, intensity, and duration.

SHADOW—General term for the thinner areas of a negative or the darker areas of an original.

SHOT—(1) Motion picture. The most basic unit of a film; a single scene; the continuous action occurring from the time the camera is turned on to the time it is turned off. (2) Still picture. A single exposure or photograph.

SHUTTER, BETWEEN-THE-LENS—A shutter whose blades operate between two elements of the

lens, as differentiated from the focal plane or behind-the-lens shutters. Sometimes applied to an iris diaphragm whose blades operate between lens elements.

SHUTTER, FOCAL-PLANE—A shutter located near the focal plane and consisting of a curtain with a slot that is pulled across the focal plane to make the exposure. The width of the slit and the speed it is moved determine the duration of the exposure.

SHUTTER RELEASE—A device to actuate a camera shutter.

SHUTTER SPEED—The length of time that light is permitted to act upon film or paper as a result of the shutter having opened and closed.

SILHOUETTE—An art term for the outline of a form in black or white that is offset by a background of the contrasting color. (PIA)

SILVER HALIDE—A compound of silver and one of the following elements known as halogens: chlorine, bromide, iodine, and fluorine. (NMA)

SLANT TRACK—Same as helical scan.

SODIUM HYDROXIDE (CAUSTIC SODA, SODIUM HYDRATE), NaOH—A deliquescent white material usually available as pellets, flakes, or sticks. Soluble in water with the liberation of heat. A very active accelerator used in high-energy developers. Concentrated solutions are quite caustic and will attack the skin, causing painful burns.

SODIUM THIOSULFATE (THIOSULFATE OF SODA, HYPO) $\text{Na}_2\text{S}_2\text{O}_3 \cdot 5\text{H}_2\text{O}$ —Colorless crystals, very soluble in water. It is the principal constituent of most fixing solutions. It may be available in the anhydrous form.

SOFT—(1) As applied to a photographic emulsion or developer, having a low contrast. (2) As applied to the lighting of a set, diffuse, giving a flat scene in which the brightness difference between highlights and shadows is small.

SOFT FOCUS—An unsharp photographic image or a special lens or exposing technique by means of which it is produced. (PIA)

SPECIFIC GRAVITY (LIQUID AND SOLID)—The ratio of the weight of a substance to the weight of an equal volume of distilled water.

SPECULAR—Like a mirror, reflecting in a regular manner so that clear images may be formed, nondiffusing.

SPOT—A contraction of “spotlight”; a lamp which projects a narrow, strong beam of light. (Verb) To remove spots from photographic prints, sometimes called “positive retouching” or “print retouching.”

SQUEEGEE—(1) A rubber blade mounted in a holder which, when drawn over the surface of a wet film or paper, removes the surface liquid. (2) Rollers used for the same purpose. (3) On continuous processing machines, air squeegees may be used that remove surface liquid by either suction or by blowing air against material being processed.

STAIN—A local or general discoloration of negatives and prints.

STEP TEST—(1) A series of exposures made with gradual increases in illumination used to determine proper exposure conditions. (2) To test for contrast or latitude, you can use a step wedge in a single exposure. (NMA)

STOP BATH—A stop bath is an acid solution used to arrest development by neutralizing the alkaline developer with which the photographic material is saturated as it leaves the developing bath.

STROBE—Designates an electronic flash lamp.

SUBTRACTIVE PRIMARIES—The three printing colors used in three-color subtractive color processes: magenta (minus green), cyan (minus red), and yellow (minus blue-violet). (PIA)

SYNCHROFLASH—Photographic arrangement whereby a photoflash lamp is timed to provide illumination at the instant when the camera shutter is wide open.

TIME BASE CORRECTOR (TBC)—An electronic accessory to a videotape recorder that helps make playbacks or transfers electronically stable. A TBC helps to maintain picture stability even in dubbing-up operations.

TIME TEMPERATURE CHART—A table showing the optimum time of development at the standard temperature for various photographic materials in a given developer or for different times of development in order to obtain equivalent development at nonstandard temperatures. (PIA)

TONE—(1) In a photographic negative or print, the degree of lightness or darkness of the various parts of the image. (2) A term applied to the color of the image in a photographic print; that is, warm, cold, sepia, and so forth.

TRANSILLUMINATE –To illuminate through a document, from the side opposite the camera.

UNDERDEVELOPMENT –Insufficient development; due to developing for too short a time, use of a weakened developer or, occasionally, too low a temperature.

UNDEREXPOSURE–Insufficient exposure of a photographic material, causing thin or weak images and a corresponding loss of detail. (PIA)

VANISHING POINT–In a perspective view, the point where parallel lines receding from the observer seem to come together.

VELOCITY OF LIGHT–Term applied to the speed of light waves in a vacuum (Co); 229,792.5 kilometers per second, or approximately 186,000 miles per second. In all other media, light travels at a slower rate.

VIDEO CASSETTE–A plastic container in which a videotape moves from a supply reel to a take-up reel. Used in all but the 1-inch VTRs.

VISIBLE SPECTRUM–The portion of the electromagnetic spectrum to which the retina is sensitive and by which we see. Extends from about 400 to 750 millimicrons in wavelengths of radiation.

VTR–Videotape recorder or recording. Includes video cassette recorders.

WASHING–Act of removing soluble chemicals from photographic layers through the agency of water, especially the removal of fixation products and hypo in order to avoid subsequent fading or discoloration of the silver image.

WATER SPOTS–Deformation of photographic gelatin layers on a film or plate due to differential drying when water drops stand on the surface and keep the gelatin wet and swollen after the surrounding gelatin has become dried and compressed. The spots have a characteristic appearance when a negative on which they occur is printed. Viscose sponges and wetting solutions (detergents) are commonly used to avoid such defects. (PIA)

WAVELENGTH–Length of a wave measured from any point on one wave to the corresponding point on the next wave; usually measured from crest to crest. Wavelength determines whether radiant energy is classed as gamma rays, X rays, or ultraviolet, visible, infrared radiant energy, or radio. Wavelength of visible radiant energy is the chief determinant of its perceived color.

WETTING AGENT–A chemical added to water to reduce surface tension, thereby improving wetting characteristics and reducing the formation of water drops. (NMA)

Y/C–The separate processing of the luminance (Y) and chrominance (C) signals.

APPENDIX II

FORMULAS

Relative Aperture: $f = \frac{F}{D}$

Hyperfocal Distance: $H = \frac{F^2}{f \times C}$

Near Distance: $ND = \frac{H \times D}{H + D}$

Far Distance: $FD = \frac{H \times D}{H - D}$

Ratio between image size and object (subject) size: $R = \frac{\text{Image size}}{\text{Object size}}$

Object Focal Distance: $F + (F \times R)$

Image Focal Distance: $F + (F \times R)$

IFGA: $\frac{I}{F} = \frac{G}{A}$

Filter Factor Exposure Compensation: $\frac{\text{ISO}}{\text{Filter Factor}}$
or
 $\text{Shutter Speed} \times \text{Filter Factor}$

Exposure: $E = I \times T$ or $H = E \times T$

Bellows Extension:

New Exposure Time $\left(\frac{BE}{FL}\right)^2 \times T$
or

Adjusted f/stop: $\frac{\text{indicated f/stop} \times \text{focal length}}{\text{lens-to-film distance}}$

Fahrenheit to Celsius: $^{\circ}F - 32 \times \frac{5}{9}$

Celsius to Fahrenheit: $^{\circ}\text{C} \times \frac{9}{5} + 32$

Changing Solution Strength: $\frac{\text{Amount Wanted} \times \text{Strength Desired}}{\text{Strength on Hand}}$

Exposure Time (in seconds) for Motion-Picture Camera: $\frac{\text{Shutter-Degree Opening}}{360 \times \text{fps}}$

Assignment Questions

<p><u>Information:</u> The text pages that you are to study are provided at the beginning of the assignment questions.</p>

ASSIGNMENT 1

Textbook Assignment: "Theory of Light and Optical Principles." Pages 1-1 through 1-37.

- | | |
|---|--|
| <p>Learning Objective: Identify principles and characteristics of light.</p> <hr/> | |
| 1-1. In what range of the electro-magnetic spectrum does light exist? | 1-6. The distance from the crest of one wave to the crest of the next wave of light describes what term? |
| 1. 1nm to 100,000nm
2. 10nm to 10,000nm
3. 100nm to 1,000nm
4. 400nm to 700nm | 1. Frequency
2. Speed
3. Wavelength
4. Distribution |
| 1-2. What theory was published by Max Planck to explain X ray, radiation, and photoelectricity? | 1-7. What color of light is made up of an even mixture of all the visible wavelengths? |
| 1. Wave motion
2. Quantum
3. Raster
4. Electromagnetic | 1. White
2. Black
3. Blue
4. Green |
| 1-3. What theory explains reflection, refraction, diffraction, and polarization? | 1-8. The spectral energy of a light source is represented by |
| 1. Wave motion
2. Quantum
3. Photo optics
4. Electromagnetic | 1. speed
2. frequency
3. wavelength
4. color temperature |
| 1-4. A nanometer is equal to what number of millimeters? | 1-9. The color temperature of red light is less than the color temperature of blue light. |
| 1. 1/10
2. 1/100
3. 1/1,000
4. 1/1,000,000 | 1. True
2. False |
| 1-5. The speed of light is always constant. | 1-10. What scale is used to measure the color temperature of light? |
| 1. True
2. False | 1. Fahrenheit
2. Celsius
3. Kelvin
4. Chromaticity |
| | 1-11. Color hue is defined as what property of color? |
| | 1. Brightness
2. Purity
3. Saturation
4. Color |

1-12. The terms dull, bright, vivid, and brilliant are used to describe what color characteristic?

1. Hue
2. Brightness
3. Saturation
4. Purity

Learning Objective: Identify ways in which light reacts with various mediums.

1-13. When light waves encounter an object, which of the following actions may take place?

1. Reflection
2. Absorption
3. Transmission
4. Each of the above

1-14. Specular light strikes a smooth surface at 60 degrees. At what angle is the light reflected?

1. 30 degrees
2. 60 degrees
3. 90 degrees
4. 120 degrees

1-15. Which of the following descriptors best defines an object that is opaque?

1. Very hard
2. Highly reflective
3. Light stopping
4. Each of the above

1-16. A change in direction that occurs when light passes from one transparent medium into another is known by what term?

1. Refraction
2. Reflection
3. Diffraction
4. Dispersion

1-17. What characteristic of light allows a lens to form an image?

1. Reflection
2. Diffraction
3. Refraction
4. Dispersion

1-18. Of the following wavelengths, which one has its speed reduced the most when it enters a medium of higher density?

1. Red
2. Yellow
3. Green
4. Blue

1-19. What term describes the ability of a prism to break up white light into its component colors?

1. Refraction
2. Diffraction
3. Dispersion
4. Polarization

1-20. A light ray is bent as it passes very close to an opaque object. What term is used to describe this event?

1. Dispersion
2. Refraction
3. Polarization
4. Diffraction

1-21. When the motion a light wave is in one direction only, the light is

1. parallel
2. polarized
3. planed
4. directionless

1-22. What type of light is seen as glare?

1. Plane polarized
2. Diffused
3. Tungsten
4. Fluorescent

Learning Objective: Recognize various sources of light and the differences between them.

- 1-23. What color of light is scattered the most by the atmosphere?
1. Red
 2. Green
 3. Yellow
 4. Blue
- 1-24. What is the approximate color temperature of overhead sunlight on a clear day?
1. 2000 K
 2. 3200 K
 3. 5400 K
 4. 60000 K
- 1-25. You have exposed daylight balanced color slide film under fluorescent light without a filter. What color cast do the finished slides have?
1. Blue
 2. Green
 3. Yellow
 4. Red
- 1-26. What is the main purpose of a lamp reflector?
1. To increase the amount of light emitted by a lamp
 2. To diffuse light
 3. To polarize light
 4. To redirect light
- 1-27. Most electronic-flash units are designed to be most efficient when they are at what distance from the subject?
1. 3 to 10 feet
 2. 6 to 12 feet
 3. 10 to 18 feet
 4. 12 to 36 feet

Learning Objective: Identify basic characteristics of photographic lenses.

- 1-28. The inherent errors of a lens are known by what term?
1. Faults
 2. Defects
 3. Aberrations
 4. Parallax
- 1-29. The inability of a lens to focus sharply both horizontal and vertical lines on the same plane is what lens aberration?
1. Astigmatism
 2. Coma
 3. Spherical
 4. Chromatic
- 1-30. The distance from the optical center of the lens to the film plane is 150mm. The image on the film is in sharp focus. The lens is focused on an object at infinity or 640 feet away. What is the focal length of this lens?
1. 50mm
 2. 85mm
 3. 135mm
 4. 150mm
- 1-31. The focal length can be changed in what type of lens?
1. Mirror
 2. Zoom
 3. Macro
 4. Anamorphic
- 1-32. What factor determines the normal focal-length lens for a camera?
1. Film size
 2. Shutter type
 3. Camera size
 4. Lens-to-film distance
- 1-33. Providing the camera-to-subject distance remains unchanged, which of the following focal-length lenses provides the greatest subject area?
1. 200mm
 2. 100mm
 3. 50mm
 4. 25mm

1-34. Which of the following focal-length lenses used at the same lens-to-film distance will produce the largest image of the subject?

1. 135mm
2. 80mm
3. 50mm
4. 25mm

1-35. The angle of field for a normal lens is within a range of how many degrees?

1. 25° to 35°
2. 45° to 55°
3. 75° to 85°
4. 95° to 105°

1-36. What type of lens has an angle of view greater than 55 degrees?

1. Telephoto
2. Mirror
3. Wide angle
4. Long-focal length

1-37. What is the final result when an image is recorded with a lens that has a large diaphragm opening?

1. Moving objects appear sharp
2. All objects within the scene appear sharp
3. Angle of view is increased
4. Only the object the lens is focused on appears sharp

1-38. Photographic perspective depends on the focal length of the lens.

1. True
2. False

1-39. The lens you are using is focused on infinity and set at f/8. The size of the aperture is 1/2 inch. What is the focal length, in inches?

1. 1
2. 2
3. 8
4. 4

Learning Objective: Recognize the function and the effects of the aperture of a lens.

1-40. The lens you are using is set at f/16 and is focused less than infinity. What is the relative aperture of the lens?

1. f/8
2. f/11
3. f/16
4. f/22

1-41. What is the relative aperture of a 6-inch lens with an effective aperture of 1.5 inches?

1. f/4
2. f/5.6
3. f/8
4. f/11

1-42. Three lenses of different focal lengths are used at the same f/stop to photograph the same subject. What lens, if any, produces the brightest image on the film plane?

1. 200mm
2. 50mm
3. 28mm
4. None

1-43. Which of the following terms describes the device within a lens that controls the amount of light passed by the lens to the film plane?

1. Concentricizer
2. Diaphragm
3. Adjuster
4. Obstructor

1-44. What term is used to describe the largest aperture of a lens?

1. Refraction index
2. Closed-down aperture
3. Lens speed
4. Optimum aperture

1-45. Which of the following f/stops represents the largest aperture?

1. f/5.6
2. f/8
3. f/22
4. f/32

1-46. You have changed the lens setting from f/5.6 to f/16. What term describes the action you have taken?

1. Stopping down
2. Opening up
3. Racking out
4. Sliding back

1-47. You have changed the f/stop setting from f/16 to f/8. What amount of light is admitted to the film plane?

1. One half
2. Two times
3. One quarter
4. Four times

1-48. A lens set to f/8 produced a correct exposure in 1 second. When you set the lens at f/4, what is the correct exposure time, in seconds?

1. 1
2. 2
3. 1/2
4. 1/4

1-49. Of the following f/stops, which one is not a standard, full f/stop?

1. f/1
2. f/2.5
3. f/5.6
4. f/45

Learning Objective: Identify factors that affect the means in which a lens focuses an image.

Figure 1A

IN ANSWERING QUESTION 1-50, REFER TO FIGURE 1A.

1-50. What object is represented as being the greatest distance from the camera?

1. A
2. B
3. C

1-51. The principal focal plane is located a total of how many inches behind a 3-inch focal-length lens?

1. 1.5
2. 6
3. 3
4. 4

1-52. As an object moves closer to the lens, what distance, if any, must the film plane to the lens change in order to keep the image in sharp focus?

1. It must be increased
2. It must be decreased
3. None

- 1-53. What distance is required between the lens and the focal plane so the image formed by a 2-inch focal-length lens is the same size as the subject?
1. 1 inch
 2. 2 inches
 3. 1.4 inches
 4. 4 inches
- 1-54. The distance the focal plane can be moved forward or backward from the plane of sharp focus and still record an acceptably sharp image is known by what term?
1. Depth of field
 2. Circle of confusion
 3. Depth of focus
 4. Hyperfocal distance
- 1-55. What term describes the distance from the lens beyond which all objects are rendered in acceptably sharp focus when the lens is set at infinity?
1. Hyperfocal distance
 2. Depth of field
 3. Depth of focus
 4. Near distance
- 1-56. What is the hyperfocal distance of a 6-inch lens set at $f/11$ when the permissible circle of confusion is 0.006 inches?
1. 2.38 feet
 2. 36.72 feet
 3. 545.45 feet
 4. 3361.11 feet
- 1-57. Your lens is set at $f/11$, the hyperfocal distance is 71 feet, and your subject is 112 feet from the camera. You should focus at what distance for maximum depth of field?
1. 35.5 feet
 2. 56.0 feet
 3. 71.0 feet
 4. 112.0 feet
- 1-58. Of the following lenses, which one provides the greatest depth of field when set at $f/5.6$ and focused on an object 6 feet from the lens?
1. 35mm
 2. 50mm
 3. 80mm
 4. 135mm
- 1-59. Which of the following factors affects depth of field?
1. Lens focal length
 2. Lens f /stop
 3. Camera-to-subject distance
 4. All of the above
- 1-60. You are using a lens focused on the hyperfocal distance which is 50 feet. What is the approximate depth-of-field range?
1. 25 feet to 75 feet only
 2. 25 feet to infinity
 3. 50 feet to infinity only
 4. 75 feet to infinity only
- 1-61. What is the depth of field of a 50mm lens set at $f/8$ with a permissible circle of confusion of 0.002 inches when it is focused on an object 20 feet from the lens?
1. 10.0 feet to 20.0 feet
 2. 15.7 feet to 23.4 feet
 3. 18.6 feet to 21.7 feet only
 4. 20.0 feet to 23.8 feet only
-
- Learning Objective: Determine the relationship between the subject/image size.
-
- 1-62. A document is 1-inch square. You must photograph it to produce a 4-inch-square image on the film. Using a 6-inch lens, what image focal distance is required?
1. 10 inches
 2. 12 inches
 3. 24 inches
 4. 30 inches

- 1-63. The size of the image formed by a lens depends on which of the following factors?
1. The size of the subject
 2. The lens-to-subject distance
 3. The lens focal length
 4. All of the above
- 1-64. A 10-inch focal-length lens is used to photograph an object 8 feet high from a distance of 28 feet. What image size is on the film plane?
1. 1.25 inches
 2. 2.50 inches
 3. 2.85 inches
 4. 5.70 inches
- 1-65. You are assigned to photograph an object 10 feet wide using a 4x5-inch camera with a 7-inch lens. You must position your camera what distance from the object to produce a 3-inch image?
1. 1.40 feet
 2. 11.65 feet
 3. 23.30 feet
 4. 46.60 feet
- 1-66. Using a 35mm camera with a 50mm lens, you have photographed a subject. However, the shooting-crew supervisor informs you that a 4x5-inch negative is required. You cannot change your shooting position. What focal-length lens should you use on the 4x5 camera to obtain approximately the same coverage produced with the 35mm camera?
1. 360mm
 2. 210mm
 3. 90mm
 4. 65mm

Learning Objective: Identify various types of lenses and their characteristics.

- 1-67. Which of the following are characteristics of a long-focal-length lens?
1. They have a reduced depth of field
 2. They decrease the apparent distance between subjects on different planes
 3. Both 1 and 2 above
 4. They introduce image distortion
- 1-68. A wide-angle lens has which of the following characteristics?
1. Increased depth of field
 2. Exaggerated linear perspective
 3. Increased apparent distance between planes
 4. All of the above
- 1-69. When photographing a building, you notice in the viewfinder that the sides of the building appear to be bending toward the center of the image area. What type of lens is on your camera?
1. Rectilinear
 2. Wide angle
 3. Normal
 4. Telephoto
- 1-70. The distortion caused by wide-angle lenses actually changes perspective.
1. True
 2. False
- 1-71. Which of the following lenses is very useful for taking pictures of extreme closeups shots?
1. Fisheye
 2. Rectilinear
 3. Telephoto
 4. Macro
- 1-72. Of the following lenses, which one is best for taking informal portraits with a 35mm camera?
1. 100mm
 2. 50mm
 3. 35mm
 4. 17mm

- 1-73. You are photographing a row of aircraft on the flight deck. Using a medium-format camera, you should use which of the following lenses to make the aircraft appear to be parked very close to each other?
1. 500mm
 2. 150mm
 3. 75mm
 4. 40mm
- 1-74. Of the following characteristics, which one is NOT representative of a mirror lens?
1. Shorter physical size
 2. Out-of-focus highlights that record as rings of light
 3. Wide range of f/stops
 4. Limited depth of field
- 1-75. What type of lens is used to change the image size without changing the lens-to-film distance?
1. Macro
 2. Zoom
 3. Mirror
 4. Telephoto

ASSIGNMENT 2

Textbook Assignment: "Light-Sensitive Materials" and "Photographic Filters." Pages 2-1 through 3-12.

<hr/> <p>Learning Objective: Identify basic characteristics of light-sensitive materials.</p> <hr/>	
2-1. What type of salts is used to make photographic film?	2-6. Exposure to light causes what invisible change to a photographic emulsion?
<ol style="list-style-type: none">1. Gelatin2. Halide3. Oxide4. Silver	<ol style="list-style-type: none">1. Film speed2. Development3. Black-metallic silver4. Latent image
2-2. Undyed silver halides are sensitive to what color of light?	<hr/> <p>Learning Objective: Identify film characteristics that you must take into consideration when selecting a type of film for a photographic assignment.</p> <hr/>
<ol style="list-style-type: none">1. Blue2. Green3. Yellow4. Red	2-7. The inherent property of a film emulsion to respond to light is known by what term?
2-3. What portion of photographic film or paper is light sensitive?	<ol style="list-style-type: none">1. Film speed2. Spectral sensitivity3. Exposure latitude4. Emulsion definition
<ol style="list-style-type: none">1. Base2. Emulsion3. Antihalation backing4. Overcoating	2-8. What organization is responsible for the approval of a uniform set of film-speed standards?
2-4. What is the primary purpose of the base portion of photographic film and paper?	<ol style="list-style-type: none">1. Eastman Kodak Company2. Morgan and Morgan Corporation3. International Standards Organization4. Film Speed Organization of America
<ol style="list-style-type: none">1. It prevents the emulsion from being damaged2. It suspends the silver halides3. It supports the emulsion4. It contains sensitizing dyes	2-9. A film may be assigned more than one film speed for which of the following reasons?
2-5. Because of the nature of the recording medium used in still video and digital cameras, they must be loaded in complete darkness.	<ol style="list-style-type: none">1. Because the film may be used in hot or cold weather2. For use with fast or slow shutter speeds3. Because the emulsion may respond differently to different qualities of light4. To provide the photographer with an option of shooting fast or slow subject motion
<ol style="list-style-type: none">1. True2. False	

- 2-10. What is/are the numerical value(s) assigned to film for exposure calculation?
1. ISO
 2. Exposure Index
 3. Both 1 and 2
 4. Light-meter Index
- 2-11. What does the term "spectral sensitivity" refer to in photographic emulsions?
1. The manner that the film responds to light only
 2. The intensity of light required to produce the proper exposure
 3. The duration of light or radiant energy required to produce a visible color image
 4. The way the emulsion responds to specific colors of light and invisible radiations
- 2-12. Colorblind emulsions are sensitive to which of the following colors of light?
1. Blue
 2. Green
 3. Red
 4. Yellow
- 2-13. Which of the following is NOT a classification of black-and white film?
1. Infrared
 2. Ultraviolet
 3. Panchromatic
 4. Orthochromatic
- 2-14. Red records on an orthochromatic film in what manner?
1. As a light-blue color
 2. As a dense deposit of silver
 3. As a clear area
 4. As a light-red color
- 2-15. To what type of radiation is a panchromatic emulsion NOT sensitive?
1. Infrared
 2. Ultraviolet
 3. Blue light
 4. Green light
- 2-16. To prevent the exposure of infrared film by UV radiation, you should use what color filter?
1. Blue
 2. Red
 3. Green
 4. Yellow
- 2-17. What areas of a black-and-white negative have the greatest amount of silver deposits?
1. Contrast points
 2. Midtones
 3. Highlights
 4. Shadows
- 2-18. What term describes the amount of silver deposit present in any area of a negative?
1. Highlight
 2. Contrast
 3. Midtone
 4. Density
- 2-19. What term describes the difference in densities between areas of a negative?
1. Contrast
 2. Latitude
 3. Emulsion definition
 4. Resolving power

2-20. Which of the following definitions best describes "emulsion latitude"?

1. The ability of a film to reproduce brightness differences
2. The amount of deviation from the correct exposure that will still produce acceptable densities
3. The evenness of the emulsion thickness applied to the film base
4. The variation in film processing time that still permits the emulsion to respond to the action of the fixing bath

2-21. What is exposure latitude?

1. The difference in negative densities
2. The amount of exposure variation that will still produce an acceptable image
3. The minimum exposure required to produce sufficient shadow detail
4. The amount of density produced by a given exposure

2-22. What factor(s) determine(s) the graininess of a negative?

1. Manufacturing
2. Exposure
3. Development
4. All of the above

2-23. All processed black-and-white film produces images with metallic silver.

1. True
2. False

2-24. The ability of a emulsion to record fine detail is known by what term?

1. Clumping action
2. Resolving power
3. Acutance
4. Graininess

2-25. The ability of an emulsion to produce sharp edges between differences in density is known by what term?

1. Clumping action
2. Resolving power
3. Acutance
4. Graininess

Learning Objective: Recognize components of black-and-white and color films.

2-26. Film is protected from friction, scratches, and abrasions before development by what part of the film?

1. Overcoating
2. Base
3. Antihalation backing
4. Noncurl coating

2-27. What part of the film prevents light from reflecting back from the base and affecting the light-sensitive silver halides?

1. Overcoating
2. Emulsion
3. Antihalation backing
4. Noncurl coating

2-28. The top emulsion layer of color film is sensitive to what color of light?

1. Blue
2. Green
3. Red
4. Yellow

2-29. What is the purpose of the yellow filter incorporated between the blue and green emulsion layers of color film?

1. To enhance the contrast
2. To prevent blue light from affecting the middle and bottom emulsion layers
3. To prevent the film from being affected by UV radiation
4. To aid in printing color negatives

- 2-30. In a color negative, what color is the image of a red subject?
1. Blue
 2. Magenta
 3. Red
 4. Cyan
- 2-31. In color-reversal film, what color is the image of a red subject?
1. Red
 2. Magenta
 3. Blue
 4. Cyan
- 2-32. Daylight color film may be used without filtration under which of the following light sources?
1. Sunlight
 2. Electronic flash
 3. Both 1 and 2
 4. "Daylight" fluorescent lights
- 2-33. As a Navy Photographer's Mate, you should only use a professional type of film.
1. True
 2. False
- 2-34. Instant picture film is very useful when used in which of the following situations?
1. Passport photographs
 2. Identification photographs
 3. Determining test exposures
 4. All of the above

Figure 2A

IN ANSWERING QUESTION 2-35, REFER TO FIGURE 2A.

- 2-35. What segment(s) of figure 2A represent(s) a sheet of film with the emulsion facing you?
1. A
 2. B
 3. C
 4. Each of the above
- 2-36. When images are stored on a still-video floppy disk, what mode(s), if any, provide(s) the highest quality image?
1. Frame only
 2. Field only
 3. Both frame and field modes provide the same image quality
 4. None
- 2-37. What number of images can be stored on a floppy disk when used in a still-video camera set on the "field" setting?
1. 20
 2. 36
 3. 50
 4. 100

Learning Objective: Identify characteristics of photographic papers.

- 2-38. When, if ever, is panchromatic printing paper used in making black-and-white prints?
1. When printing high-contrast negatives
 2. When printing low-contrast negatives
 3. When using color negatives to produce black-and-white prints
 4. Never, panchromatic papers are only used for making color prints

2-39. The top emulsion layer of variable contrast, black-and-white paper is sensitive to (a) what color of light and produces (b) what type of contrast?

1. (a) Blue (b) high
2. (a) Green (b) low
3. (a) Blue (b) low
4. (a) Green (b) high

2-40. You are using variable contrast, black-and-white printing paper. The contrast of the print is primarily controlled by what stage of printing.

1. By different exposure times
2. By manipulating the processing time
3. By changing the angle of the projected image
4. By using filters

2-41. Which of the following color papers does NOT directly make a positive image from a color negative?

1. Ektacolor
2. Fujicolor
3. Ektachrome
4. Each of the above

2-42. The top emulsion layer of color paper produces what color of dye?

1. Red
2. Cyan
3. Blue
4. Yellow

2-43. Which of the following paper surfaces should you use to show fine detail in a print?

1. Matte
2. Semimatte
3. Pearl
4. Glossy

2-44. Photographic paper and film should be stored in a location that does not exceed what (a) temperature and (b) relative humidity?

1. (a) 75°F (b) 75%
2. (a) 50°F (b) 50%
3. (a) 75°F (b) 50%
4. (a) 50°F (b) 75%

2-45. You notice that the expiration date on a case of aerial film has expired. Which of the following actions should you take?

1. Discard the film immediately
2. Conduct photographic tests before using the film
3. Ignore the expiration date and use the film for an aerial mission
4. Freeze the film for 24 hours and then use it for Antarctic missions only

Learning Objective: Identify principal types of filters used in black-and-white and color photography.

2-46. What primary factor determines the effectiveness of a photographic filter?

1. The ability of the emulsion to respond to the light passed by the filter
2. The density of the filter
3. The color of the filter
4. The chemicals in which the light-sensitive emulsion is processed

2-47. It is not necessary to use color filters with black-and-white emulsions because only shades of gray are produced.

1. True
2. False

- 2-48. Contrast filters should be used for black-and-white photography for which of the following reasons?
1. To exaggerate a color
 2. To reduce a color
 3. To eliminate a color
 4. Each of the above
- 2-49. You are tasked to copy a document on white paper that contains red, green, and blue lines. You do not want the green lines to be noticeable in the final print. What color filter should you use?
1. Magenta
 2. Red
 3. Green
 4. Cyan
- 2-50. You are using black-and-white panchromatic film under daylight conditions. What color filter should you use to reproduce the colors of the scene with the same brightness relationship as seen by the human eye?
1. No. 8 (yellow)
 2. No. 23A (light Red)
 3. No. 34A (violet)
 4. No. 4 (cyan)
- 2-51. You are photographing a landscape scene with black-and-white panchromatic film. Which of the following filters should you use to reduce the appearance of haze in the final print?
1. Blue
 2. Cyan
 3. Red
 4. Magenta
- 2-52. Light balancing filters are available in what two colors?
1. Yellow and green
 2. Green and red
 3. Blue and red
 4. Blue and yellow
- 2-53. What color of light balancing filter should you use to lower the color temperature of light?
1. Yellow
 2. Green
 3. Red
 4. Blue
- 2-54. What color of light balancing filter should you use to raise the color temperature of light?
1. Yellow
 2. Green
 3. Red
 4. Blue
- 2-55. What type of filter should you use to make minor adjustments to the color quality of light used to expose film?
1. Light balancing
 2. Conversion
 3. Color compensating
 4. Correction
- 2-56. What instrument should you use to determine the color temperature of a light source?
1. Exposure meter
 2. Color analyzer
 3. Color temperature meter
 4. Spot meter
- 2-57. What are the two series of conversion filters?
1. 80 and 81
 2. 80 and 85
 3. 85 and 86
 4. 85 and 90
- 2-58. What color conversion filter is used to expose daylight-type film under tungsten light?
1. Blue
 2. Green
 3. Amber
 4. Cyan

- 2-59. When exposing color film under fluorescent light, you should use what type of filter?
1. Color compensating
 2. Conversion
 3. Correction
 4. Light balancing
- 2-60. What maximum number of CC filters can be used effectively on a camera lens?
1. One
 2. Two
 3. Three
 4. Four
- 2-61. A CC20M filter has a peak density of 0.20 to what color of light?
1. Yellow
 2. Blue
 3. Magenta
 4. Green
- 2-62. What is the complementary color of green?
1. Yellow
 2. Blue
 3. Cyan
 4. Magenta
- 2-63. What combination of complementary colors make up red?
1. Yellow and cyan
 2. Magenta and yellow
 3. Cyan and yellow
 4. Magenta and cyan
- 2-64. What is the equivalent filter pack of a 50G + 20R + 10B CC-filter pack?
1. 40G + 10R
 2. 50G + 20R + 0 ND
 3. 60G + 30R + 20B
 4. 80 ND
- 2-65. Which of the following filters is NOT selective in the color of light it absorbs?
1. Correction
 2. Neutral density
 3. Color compensating
 4. Conversion
- 2-66. What ND filter is used to reduce exposure by two f/stops?
1. .20
 2. 2.00
 3. .30
 4. .60
- 2-67. What color filter is most effective for cutting haze?
1. Red
 2. Yellow
 3. Blue
 4. Green
- 2-68. For which of the following situations may polarizing filters be used?
1. To reduce reflections from water
 2. To reduce the effect of haze
 3. To increase color saturation
 4. Each of the above
- 2-69. Your light meter indicates an exposure of 1/500 sec at f/11. You then add an orange filter with a filter factor of 4. What is your new exposure setting?
1. 1/500 sec at f/22
 2. 1/500 sec at f/8
 3. 1/250 sec at f/11
 4. 1/125 sec at f/11
-
- Learning Objective: Identify the uses for filters in photographic darkrooms.
-

- 2-70. Which of the following light sources is used as a safelight in black-and-white print rooms?
1. Mercury vapor
 2. Sodium vapor
 3. Quartz halogen
 4. Fluorescent
- 2-71. You have a black-and-white negative with high contrast. What color variable-contrast printing filter should you use to produce a print with normal contrast?
1. Blue
 2. Green
 3. Yellow
 4. Magenta
- 2-72. Which of the following filters should always be used in a color printing system?
1. Color compensating
 2. Dichroic
 3. Color printing
 4. Ultraviolet absorbing
- 2-73. What type of filter works on the principle of wavelength interference, rather than wavelength absorption?
1. Color compensating
 2. Color printing
 3. Safelight
 4. Dichroic
- 2-74. CP filters are used the same as CC filters in a color printing system.
1. True
 2. False
- 2-75. Photographic filters should not be exposed to heat above what maximum temperature?
1. 100°F
 2. 120°F
 3. 150°F
 4. 200°F

ASSIGNMENT 3

Textbook Assignment: "Still cameras and Controls." Pages 4-1 through 4-31.

Learning Objective: Recognize similarities and differences among the various categories of cameras and the advantages and disadvantages of each.

Learning Objective: Identify various focusing systems and the importance of subject focus within a scene.

- | | |
|---|--|
| <p>3-1. Which of the following size cameras is most suitable for an assignment that requires a large number of exposures that must be taken in rapid succession?</p> <ol style="list-style-type: none">1. 35mm2. 2 1/4 x 2 3/43. 4x54. 8x10 <p>3-2. Which of the following focusing systems does NOT permit you to see depth of field in the viewfinder?</p> <ol style="list-style-type: none">1. SLR2. TLR3. Ground glass4. Rangefinder <p>3-9. As a Navy Photographer's Mate, you want everything in your photographs to be in sharp focus.</p> <ol style="list-style-type: none">1. True2. False <p>3-10. What type of focusing should you use to draw attention to the subject in a photograph?</p> <ol style="list-style-type: none">1. Selective2. Chosen3. Pointed4. Impulse |
|---|--|

3-11. Which of the following focal-length lenses used at a given f/stop and lens-to-film distance provides the greatest selective focus affect?

1. 1000mm
2. 400mm
3. 135mm
4. 50mm

3-12. Which of the following factors does NOT affect depth of field?

1. f/stop
2. Lens focal length
3. Shutter speed
4. Subject distance

Learning Objective: Identify purpose and effects of the camera aperture.

3-13. Which of the following camera controls affects the intensity of light falling on the film plane?

1. Shutter
2. Aperture
3. Intensity compensator
4. Preview actuator

3-14. What is the most important factor in controlling depth of field?

1. Shutter speed
2. Subject distance
3. Lens focal length
4. f/stop

3-15. With a given camera and all camera controls remaining constant, what subject distance, in feet, results in the greatest depth of field?

1. 30
2. 20
3. 10
4. 5

3-16. What area of a lens produces the sharpest image?

1. The central part
2. The outer edges
3. Either 1 or 2 above

3-17. Stopping down a lens increases depth of field. In what way, if any, does this action affect image sharpness?

1. It increases overall image sharpness
2. It decreases overall image sharpness
3. None

3-18. The optimum or critical aperture of a lens is generally at what f/stop setting?

1. Wide open
2. Two f/stops from wide open
3. f/11
4. f/32

Learning Objective: Identify purpose and effects of the camera shutter.

3-19. What is the primary function of a camera shutter?

1. To limit the intensity of light emitted to the film
2. To control the quality of light passed to the film
3. To regulate the amount of time that light is permitted to act on the film
4. To stop image motion by limiting the frequency of wave motion permitted to pass through the lens

3-20. Which of the following shutter speeds can be used when a leaf shutter is used with an electronic flash?

1. 1/30 second
2. 1/125 second
3. 1/500 second
4. Each of the above

3-21. What is the primary function of the camera shutter?

1. To control the duration of exposure
2. To control subject movement
3. Both 1 and 2 above
4. To control depth of field

3-22. When increasing the camera shutter speed, you must take what action to expose the film properly?

1. Close down the aperture
2. Open up the aperture
3. Add an ND filter
4. Change the film-speed setting to a higher number

3-23. What sacrifice is made when you increase the camera shutter speed?

1. Camera movement is more apparent
2. A shorter focal-length lens must be used
3. Some depth of field is lost
4. Image sharpness

3-24. You must stop subject motion but cannot afford to loose depth of field. Which of the following actions should you take?

1. Select a faster film
2. Increase the camera-to-subject distance
3. Select a shorter focal-length lens
4. All of the above

3-25. A shutter speed of 1/250 second is required to freeze image motion acceptably. Which of the following shutter speeds can also be used to record the same image motion?

1. 1/30
2. 1/60
3. 1/125
4. 1/500

3-26. When handholding a camera with a 100mm lens, what is the slowest shutter speed you should use?

1. 1/30
2. 1/60
3. 1/125
4. 1/250

3-27. When you are photographing a moving object, which, if any, of the following shutter speeds stops image motion?

1. 1/250
2. 1/500
3. 1/1000
4. None of the above

3-28. Which of the following factors limits the time the image is allowed to move across the film plane?

1. The interval of exposure
2. The direction of subject movement
3. Subject speed
4. Lens focal length

Figure 3A

IN ANSWERING QUESTION 3-29, REFER TO FIGURE 3A.

3-29. From a given camera-to-subject distance, what scene requires the fastest shutter speed to stop image movement?

1. A
2. B
3. C
4. D

Learning Objective: Recognize factors that affect the exposure of photographic film.

3-30. What two factors control camera exposure?

1. Lens speed and film speed
2. Shutter speed and lens aperture
3. Lens aperture and film speed
4. Film speed and reflected light quality

3-31. Your light meter indicates that 1/500 second at f/5.6 will properly expose the film. However, you prefer greater depth of field in the scene. Which of the following equivalent exposures should you use?

1. 1/1000 second at f/4
2. 1/250 second at f/11
3. 1/125 second at f/8
4. 1/60 second at f/16

3-32. Which of the following equations represents exposure?

1. $E = I + T$
2. $H = E \div T$
3. $E = I \times T$
4. $I = E \times T$

3-33. Your light meter indicates an exposure of 1/60 second at f/4 with Ektachrome ISO 100 film. You then change the film in the camera with Ektachrome ISO 400 film. When photographing the same subject under the same lighting conditions, which of the following camera settings should you make?

1. 1/60 second at f/5.6
2. 1/60 second at f/8
3. 1/500 second at f/4
4. 1/500 second at f/8

3-34. On a clear, bright, and cloudless day, the intensity of light remains constant.

1. True
2. False

DAYLIGHT CONDITIONS	
A.	Bright or hazy sun on light sand or snow
B.	Bright
C.	Cloudy bright
D.	Cloudy
E.	Heavy overcast or shade

Figure 3B

IN ANSWERING QUESTIONS 3-35 THROUGH 3-39, REFER TO FIGURE 3B AND SELECT THE DAYLIGHT CONDITION THAT BEST APPLIES TO THE STATEMENT USED AS THE QUESTION.

3-35. The type of daylight upon which basic exposure for an average scene is based:

1. A
2. B
3. C
4. D

3-36. Unobstructed daylight at the beach:

1. A
2. B
3. C
4. D

3-37. Completely diffused daylight:

1. A
2. B
3. C
4. D

3-38. Soft shadows:

1. A
2. B
3. C
4. E

3-39. The sun is not visible and eight times the basic exposure is required:

1. E
2. D
3. c
4. B

IN ANSWERING QUESTIONS 3-40 THROUGH 3-42, USE THE FOLLOWING INFORMATION: THE BASIC EXPOSURE FOR A SCENE IS 1/250 SECOND AT f/16 WITH FRONT SUN LIGHTING.

3-40. Using a shutter speed of 1/250 second, you should use which of the following f/stops when the scene is sidelighted?

1. f/4.5
2. f/5.6
3. f/8
4. f/11

3-41. Which of the following exposures can you use when the scene is backlighted?

1. 1/250 at f/8
2. 1/125 at f/11
3. 1/60 at f/16
4. Each of the above

3-42. Which of the following exposures should you use to produce a silhouette of the scene when it is backlighted?

1. 1/125 at f/32
2. 1/125 at f/22
3. 1/250 at f/16
4. 1/250 at f/11

3-43. You are copying a chart with a 5-inch focal-length lens and a bellows extension of 10 inches. Your handheld light meter indicates an exposure of 1/60 second at f/5.6. With the aperture remaining at f/5.6, you should use what exposure time to expose the film properly?

1. 1/60
2. 1/30
3. 1/15
4. 1/8

3-44. A 6-inch focal-length lens has a bellows extension of 16.5 inches. Your handheld light meter indicates an exposure of 1 second at f/22. What f/stop should you use to expose the film?

1. f/22
2. f/16
3. f/11
4. f/8

IN ANSWERING QUESTIONS 3-45 THROUGH 4-48, USE THE FOLLOWING INFORMATION: THE CORRECT EXPOSURE FOR A GIVEN SCENE IS 1/125 SECOND AT f/11 USING ISO 200 FILM.

3-45. Which of the following exposures should you use when the scene is photographed with ISO 100 film?

1. 1/250 at f/8
2. 1/250 at f/11
3. 1/125 at f/8
4. 1/125 at f/11

3-46. Which of the following f/stops should you use when the scene is photographed with ISO 100 film with a shutter speed of 1/250 second?

1. f/8
2. f/5.6
3. f/4.5
4. f/4

3-47. Which of the following f/stops can you use when the scene is photographed with ISO 400 film with a shutter speed of 1/125 second?

1. f/32
2. f/22
3. f/16
4. f/8

3-48. Which of the following exposures can you use when the scene is photographed with ISO 400 film?

1. 1/1000 at f/5.6
2. 1/500 at f/8
3. 1/250 at f/11
4. Each of the above

3-49. The f/16 rule for exposure calculation only applies to black-and-white photography.

1. True
2. False

Learning Objective: Identify various methods used in determining exposure with a light meter.

3-50. What means provides the most consistent way of determining film exposure?

1. Film data sheets
2. f/16 rule
3. Pocket calculator
4. Light meter

3-51. You are taking an incident light-meter reading. From what position should the light-meter reading be taken?

1. Subject
2. Camera
3. Light source

3-52. You are taking a reflected light-meter reading. You should point the camera in what direction?

1. Toward the subject
2. Toward the camera
3. Toward the light source

3-53. What type of light meter has a diffusing dome that covers the photoelectric cell?

1. Spot
2. Reflected
3. Incident
4. Inversion

3-54. You are using black-and-white film to photograph a green car. You take a reflected light-meter reading from the car. In a properly exposed and processed print, the car has what appearance?

1. Bright white
2. Middle gray
3. Dark black

3-55. You are photographing an average contrast scene and you base your camera exposure on a reflected light-meter reading from the shadow area. After it has been processed properly, the negative has what appearance?

1. Detail in the shadow areas only
2. Washed-out highlights only
3. Both 1 and 2 above
4. Very high contrast

- 3-56. You are taking an overall reflected light-meter reading of a subject that has almost equal areas of highlights and shadows. What type of light-meter reading are you taking?
1. Brightness range
 2. Darkest object
 3. Brightest object
 4. Integrated
- 3-57. You have taken an average light-meter reading of a predominately light scene. The meter indicates an exposure of 1/250 second at f/11. Which of the following exposures should you give the film to reproduce shadow detail?
1. 1/125 at f/11
 2. 1/500 at f/11
 3. 1/125 at f/8
 4. 1/1000 at f/5.6
- 3-58. You took two light-meter readings from a scene. One reading was taken from the darkest object with which you desire details and the other was taken from the lightest area where detail is desired. However, these two objects do not represent the darkest or lightest objects within the scene. What type of reflected light-meter reading did you take?
1. Integrated
 2. Brightness range
 3. Average
 4. Substitution
- 3-59. You are photographing a Navy ship that is probably too distant to get an accurate light-meter reading. You then base your exposure on a gray card. What method of light-meter reading did you use?
1. Average
 2. Integrated
 3. Brightness range
 4. Substitution
- 3-60. You are photographing an average scene but take a light-meter reading from a white card. You desire detail in both shadow and highlight areas. Which of the following exposure compensations should you take?
1. Close down two f/stops
 2. Close down one f/stop
 3. Open up two f/stops
 4. Open up one f/stop
- 3-61. Which of the following statements regarding exposure bracketing is NOT true?
1. Bracketing is permissible for all films, both black and white and color
 2. Bracketing produces varying exposures
 3. Bracketing can be used but precise exposure for color slide film is required
 4. Bracketing should not be used for black-and-white transparencies
- 3-62. You have overexposed color reversal film by one f/stop and have processed the film normally. The film has what general appearance?
1. It is very dark
 2. It is washed out
 3. It has more color saturation
 4. It has excessive contrast
- 3-63. You have processed a roll of negatives normally. Each frame of the roll appears to be overexposed by one f/stop. What is the probable cause?
1. The light meter was set to the wrong ISO
 2. Light entered the viewfinder while the light-meter reading was being taken
 3. A very bright area of the scene influenced the light meter
 4. The batteries in the light meter were too weak

Learning Objective: Recognize various functions of a view camera.

3-64. Of the following types of cameras, which one provides movements and adjustments that permit distortion correction?

1. Single-lens reflex
2. Twin-lens reflex
3. View
4. Direct-vision viewfinder

3-65. View cameras have all but which of the following parts?

1. Monorail
2. Bellows
3. Ground glass
4. Viewfinder

VIEW CAMERA CONTROL

- A. Front swing
- B. Rear swing
- C. Front tilt
- D. Rear tilt
- E. Rising and falling front
- F. Sliding front
- G. Sliding rear

Figure 3C

IN ANSWERING QUESTIONS 3-66 THROUGH 3-71, REFER TO FIGURE 3C AND SELECT THE VIEW-CAMERA CONTROL THAT PROVIDES THE CORRECTION USED AS THE QUESTION.

3-66. Centers the image vertically:

1. C
2. D
3. E
4. F

3-67. Centers the image horizontally:

1. A
2. C
3. E
4. G

3-68. Controls distortion of the vertical plane:

1. B
2. D
3. E
4. G

3-69. Controls distortion of the horizontal plane:

1. B
2. D
3. F
4. G

3-70. Increases depth of field of the horizontal plane:

1. A
2. C
3. E
4. F

3-71. Increases depth of field of the vertical plane:

1. A
2. C
3. E
4. G

3-72. When you are initially setting up the view camera, all controls are lined up and no corrective movements are set. What is this position called?

1. Set up
2. Initial
3. Neutral
4. Starting

3-73. What total number of vertical or horizontal planes can be corrected with a view camera?

1. One
2. Two
3. Three
4. Four

Learning Objective: Recognize differences and similarities of electronic and conventional cameras.

- 3-74. Which of the following electronic cameras provides the highest resolution?
1. Still video
 2. Digital
 3. Analog
 4. Each provides the same resolution
- 3-75. How does the angle of view of a DCS camera compare to the angle of view of a 35mm camera?
1. They are identical
 2. It is less than the 35mm
 3. It is greater than the 35mm

ASSIGNMENT 4

Textbook Assignment: "Basic Photographic Techniques." Pages 5-1 through 5-37.

Learning Objective: Identify general guidelines used in holding cameras steady.

- | | |
|--|---|
| <p>4-1. What is the best way to support a camera?</p> <ol style="list-style-type: none">1. By using a tripod2. By handholding it3. By holding it against a building4. By using a neck strap <p>4-2. Under normal circumstances, you should NOT handhold a camera at shutter speeds that exceed what exposure time?</p> <ol style="list-style-type: none">1. 1/500 sec2. 1/250 sec3. 1/125 sec4. 1/60 sec <p>4-3. Holding the camera steady is most critical when using what focal-length lens?</p> <ol style="list-style-type: none">1. 35mm2. 50mm3. 100mm4. 200mm <p>4-4. When handholding a camera with a 250mm focal-length lens, you should use which of the following shutter speeds?</p> <ol style="list-style-type: none">1. 1/250 sec2. 1/125 sec3. 1/60 sec4. 1/30 sec <p>4-5. What method(s) is/are used to prevent camera shake?</p> <ol style="list-style-type: none">1. Locking the mirror up on an SLR camera2. A tripod3. A cable release4. Each of the above | <p>4-6. To obtain high-quality photographs, you must always use a tripod.</p> <ol style="list-style-type: none">1. True2. False <p>4-7. The use of a monopod is NOT recommended below what shutter speed?</p> <ol style="list-style-type: none">1. 1/15 sec2. 1/30 sec3. 1/60 sec4. 1/125 sec <hr/> <p>Learning Objective: Identify elements of photographic composition.</p> <hr/> <p>4-8. For photographers to be creative, they must have which of the following attributes?</p> <ol style="list-style-type: none">1. An ability to select state of the art equipment2. An ability to handhold the camera at slow shutter speeds3. An ability to see what the camera sees4. An ability to selectively see only important details within a scene <p>4-9. Photographic composition can be improved by which of the following methods?</p> <ol style="list-style-type: none">1. By looking all around within the viewfinder2. By practice only3. By analyzing photographs used in various medias4. All of the above |
|--|---|

- 4-10. A photograph should have what maximum number of center(s) of interest?
1. One
 2. Two
 3. Three
 4. Four
- 4-11. Which of the following methods should you NOT use to draw viewer attention to the center of interest in a photograph?
1. Compose the subject with more than one object
 2. Use a contrasting background to separate the subject
 3. Place the subject in the center of the picture whenever possible
 4. Use lines to draw attention to the subject
- 4-12. You are photographing a scene and people are included, but they are not the center of interest. The people should be composed in the photograph in what manner?
1. In the foreground only
 2. Looking at the subject
 3. As far from the subject as possible
 4. Looking directly into the camera
- 4-13. Which of the following statements regarding simplicity in photographic composition is true?
1. Because of today's advanced technology, a photograph should not be simple
 2. Simple pictures are monotonous and are rejected by most viewers
 3. Simple pictures can be used to make a clear, strong statement
 4. The most successful photographers limit simplicity by having at least two points of interest in each picture
- 4-14. You are photographing the CO of your ship and want him to appear in the picture as a domineering man. What camera angle should you use?
1. Low
 2. High
 3. Eye level
- 4-15. You are photographing a person who is running. What viewpoint should you use to enhance the feeling of speed?
1. Low
 2. High
 3. Eye level
- 4-16. You are photographing a refugee child. From what viewpoint should you take the picture to emphasize the illusion of little strength?
1. Low
 2. High
 3. Eye level
- 4-17. In a photograph, two objects, one on each side of the picture, appear to have equal weight. However, the picture is not symmetrical. What type of balance, if any, has been achieved?
1. Asymmetrical
 2. Informal
 3. Formal
 4. None
- 4-18. A photograph shows several objects. There is an obvious difference in size and weight of the objects. However, the picture still gives the illusion of balance. What type of balance, if any, has been achieved?
1. Formal
 2. Informal
 3. Symmetrical
 4. None

4-19. Which of the following statements concerning photographic balance is NOT true?

1. Objects in the upper part of a picture appear to have more weight than objects in the lower part of the picture
2. Objects close to the middle of a picture appear lighter than objects at the edge of the picture
3. Irregular shapes give the impression of being lighter than regular shapes
4. When an object is isolated, the weight of the object appears to decrease

4-20. In most photographs, an object within the picture is first identified by

1. weight
2. tone
3. form
4. shape

4-21. What is the three-dimensional equivalent of shape?

1. Weight
2. Tone
3. Form
4. Balance

4-22. Which of the following photographic techniques best emphasizes the shape of an object?

1. Silhouette
2. Balance
3. Texturizing
4. Three-dimensional lighting

Learning Objective: Identify methods in which lines are used for photographic composition.

4-23. Lines that lead the eye or direct attention within a photograph are known by what term?

1. Lines of direction
2. Lines of unification
3. Leading lines
4. Linear-perspective lines

Figure 4A

IN ANSWERING QUESTIONS 4-24 THROUGH 4-36, REFER TO FIGURE 4A. SELECT THE LEADING LINE USED TO PRODUCE THE MOOD THAT IS USED AS THE QUESTION.

4-24. Strength:

1. A
2. B
3. C
4. D

4-25. Graceful movement:

1. A
2. B
3. C
4. D

4-26. Peace:

1. D
2. C
3. B
4. A

4-27. Dignity:

1. A
2. B
3. C
4. D

4-28. Action:

1. D
2. C
3. B
4. A

4-29. Rigidity:

1. A
2. B
3. C
4. D

4-30. Quietness:

1. D
2. C
3. B
4. A

4-31. Smoothness:

1. A
2. B
3. C
4. D

4-32. Grace:

1. D
2. C
3. B
4. A

4-33. Power:

1. D
2. C
3. B
4. A

4-34. Speed:

1. A
2. B
3. C
4. D

4-35. Tranquility:

1. A
2. B
3. C
4. D

4-36. Solidarity:

1. A
2. B
3. C
4. D

Learning Objective: Recognize compositional guidelines in which patterns are used for photography.

4-37. The use of patterns can provide which of the following effects in photographic composition?

1. Support of the elements within a picture
2. Add interest to the picture
3. Overwhelm the viewer
4. Each of the above

4-38. What is the most common pattern used in photographic composition?

1. Line
2. Shape
3. Color
4. Tone

4-39. What key element of composition provides apparent depth to photographs?

1. Lines
2. Shape
3. Shadows
4. Texture

Learning Objective: Identify methods used to draw viewer attention to the center of interest in a photograph.

4-40. Which of the following elements of photographic composition can you use to draw viewer attention to the center of interest?

1. Lighting
2. Texture
3. Contrast
4. All of the above

- 4-41. The view of a gray ship on a foggy morning is an example of what type of scene?
1. Low contrast
 2. Flat
 3. Both 1 and 2 above
 4. Contrasty
- 4-42. The view of a white sailboat in dark-blue water on a clear, sunny day is an example of what type of scene?
1. Low contrast
 2. Flat
 3. Both 1 and 2 above
 4. Contrasty
- 4-43. A photographic technique used to draw viewer attention to the center of interest by surrounding the subject with related objects is known by what term?
1. Keystoning
 2. Framing
 3. High keying
 4. Desegregation
- 4-44. Which of the following techniques can you use to separate the subject from the foreground or background?
1. A large f/stop
 2. Pan the subject
 3. Move in closer to the subject
 4. All of the above
- 4-45. What aspect of good composition is used when the viewer of a photograph gets a feeling of volume, space, depth, and distance?
1. Background
 2. Foreground
 3. Perspective
 4. Framing

Learning Objective: Recognize various types of perspectives and how they are used in photographic composition.

TYPES OF PERSPECTIVE

- A. Linear
- B. Rectilinear
- C. Vanishing Point
- D. Height
- E. Overlap
- F. Dwindling Size
- G. Volume
- H. Atmospheric

Figure 4B

IN ANSWERING QUESTIONS 5-46 THROUGH 5-54, REFER TO FIGURE 4B. SELECT THE TYPE OF PERSPECTIVE THAT BEST APPLIES TO THE STATEMENT USED AS THE QUESTION.

- 4-46. Two parallel roads seem to converge in the background of the picture:
1. A
 2. D
 3. F
 4. H
- 4-47. Straight, parallel, horizontal lines in the subject are recorded on the film as straight lines:
1. A
 2. B
 3. D
 4. H
- 4-48. Parallel lines in a photo seem to meet outside of the picture:
1. A
 2. C
 3. E
 4. H

- 4-49. The distance from the bottom of a picture where the base of an object on the ground begins:
1. D
 2. E
 3. F
 4. G
- 4-50. Several objects within a photograph partly hide one another:
1. C
 2. D
 3. E
 4. G
- 4-51. A number of similar objects within a photograph are shown as different sizes:
1. B
 2. D
 3. F
 4. G
- 4-52. The size of objects within a photograph gives the viewer a clue as to distance:
1. A
 2. C
 3. E
 4. F
- 4-53. The length of shadows provides an idea of the image size of the subject:
1. B
 2. D
 3. E
 4. G
- 4-54. A photograph shows distant objects somewhat obscured by haze:
1. H
 2. F
 3. D
 4. C
- 4-55. Which of the following factors affect linear perspective?
1. Lens-to-subject distance and lens focal length
 2. Lens-to-subject distance and object size
 3. Object size and lens focal length only
 4. Object size and object-to-camera distance
- 4-56. What type of perspective is produced by a panoramic lens?
1. Concave
 2. Cylindrical
 3. Rectilinear
 4. Convex
- 4-57. Two identical objects at different distances from the camera are recorded on film in different contrasts. This difference in contrast provides the viewer with what perception?
1. Color saturation
 2. Brightness
 3. Distance
 4. Sharpness
-
- Learning Objective: Identify that various lighting conditions affect the appearance of the subject.
-
- 4-58. Which of the following terms best describes color saturation?
1. Chroma
 2. Brightness
 3. Hue
 4. Value
- 4-59. Which of the following statements concerning front lighting on a clear day is true?
1. It gives an impression of depth to the photograph
 2. It adds a flattened effect
 3. It emphasizes the texture of the subject
 4. It aides in bringing out the finer details of the subject

4-60. You are tasked to photograph the flight deck of your ship after a new coat of non-skid has been applied. What time of day is best to photograph the flight deck to emphasize the texture of the newly applied non-skid?

1. 1000
2. Noon
3. 1400
4. Early morning

4-61. What type of lighting should you use outdoors to produce a silhouette photograph?

1. Back
2. Side
3. Front
4. 45 degree

4-62. You have processed a roll of daylight-balanced slide film. After removing the film from the dryer, you notice all of the frames taken indoors have a greenish cast. Which of the following light sources was most likely used to photograph the indoor scenes?

1. Electronic flash
2. Tungsten
3. Sodium vapor
4. Fluorescent

Learning Objective: Identify proper techniques used in producing images with electronic-flash units.

4-63. Which of the following factors pertaining to electronic-flash units always remains constant?

1. The f/stop being used
2. The effective candlepower seconds (ECPS)
3. The guide number
4. The film speed

4-64. What two factors are used to determine the guide number of an electronic flash?

1. ECPS and flash-to-subject distance
2. Film speed and flash-to-subject distance
3. ECPS and film speed only
4. f/stop and flash-to-subject distance

4-65. Which of the following is NOT a factor in obtaining correct exposures with an electronic flash and a lens with a leaf shutter?

1. Shutter speed
2. ISO of the film
3. Flash-to-subject distance
4. f/stop

4-66. Of the following flash techniques, which one is least desirable when you are photographing people?

1. Position the flash above the lens
2. Bounce the light from a white ceiling
3. Position the flash below the lens
4. Place diffusion material in front of the flash

4-67. Which of the following actions should you take to minimize the affect of red eye?

1. Have the subject look directly into the lens
2. Move the flash away from the lens axis
3. Move the flash closer to the lens axis
4. Reduce the ambient room light

4-68. You are using the bounce-lighting technique with an electronic flash set to "manual." The flash-to-ceiling-to-subject distance is 14 feet. The guide number of the flash is 220. What f/stop should you use to expose the film correctly?

1. f/16
2. f/11
3. f/8
4. f/5.6

4-69. You are using an electronic-flash unit. Which of the following techniques should you use to minimize distracting background shadows?

1. Hold the flash above the lens
2. Bounce the flash off the ceiling or bulkhead
3. Diffuse the light from the flash unit
4. Each of the above

4-70. What is the best general lighting ratio for both black-and-white and color photography?

1. 1:1
2. 2:1
3. 3:1
4. 5:1

4-71. You are using two flash units with the same ECPS to illuminate the subject. You should place (a) the main light and (b) the fill light at which of the following distances from the subject to achieve a 3:1 lighting ratio?

1. (a) 8 feet (b) 11 feet
2. (a) 6 feet (b) 6 feet
3. (a) 4 feet (b) 16 feet
4. (a) 4 feet (b) 8 feet

4-72. A common occurrence with the synchro-sunlight technique is it produces images of the subject that appear as though they were taken at night with a single flash unit. What is the most probable cause of this problem?

1. The flash unit was not powerful enough
2. The flash illumination overpowered the sunlight
3. The aperture used was too wide
4. The lens was not synchronized with the flash unit

4-73. What is the first step in calculating synchro-sunlight exposure?

1. Determine the correct daylight exposure
2. Determine the desired flash-to-subject distance
3. Establish the camera-to-subject distance
4. Establish the camera-to-flash distance

4-74. You are using an electronic flash unit to light a subject 20-feet away at night. The indicated f/stop on the flash unit is f/11. What f/stop should you use to expose the subject?

1. f/16
2. f/11
3. f/8
4. f/5.6

4-75. You are using two flash units of equal intensity that are equidistant from the subject to illuminate the same area of the subject. The calculated f/stop for one flash unit is f/16. What f/stop should you use to expose the image?

1. f/11
2. f/16
3. f/22
4. f/32

ASSIGNMENT 5

Textbook Assignment: "Photographic Assignments." Pages 6-1 through 6-44.

Learning Objective: Select equipment and techniques best suited for photographing people.

- 5-1. Which of the following statements will best determine your success as a Navy Photographer's Mate?
1. Use only state-of-the-art equipment
 2. Plan for each of your assignments
 3. Use professional film only
 4. Use a 4x5 view camera for the majority of your photographic assignments
- 5-2. The UIC of your imaging facility is 32509. Which of the following serial numbers best represents a local serial number for a camera assigned to your unit?
1. L-069
 2. L/S 32509-069
 3. 069-L-32509
 4. 32509-069
- 5-3. When photographing people, you should strive to achieve which of the following objectives?
1. Display the subject's character
 2. Identify the person clearly only
 3. Exaggerate the facial features of the subject
 4. Always portray the subject in a pleasing, flattering manner
- 5-4. For you to make a candid photograph of a person, the subject must not know that his/her photograph is being taken.
1. True
 2. False
- 5-5. You should normally select which of the following lenses for a 35mm camera to shoot candid photographs?
1. Fisheye
 2. 35mm
 3. 50mm
 4. 135mm
- 5-6. Which of the following statements regarding the technique of framing people in their environment is true?
1. The "frame" should be a subtle part of the photo
 2. The "frame" should be exaggerated
 3. The "frame" must completely surround the subject
 4. The "frame" should be in front of the subject
- 5-7. You are photographing people working in their environment. Which of the following aspects of the finished product is extremely important?
1. The face of the subject must be in full view
 2. The subject must be actually working
 3. The props used in the photograph must be technically correct
 4. A low angle should be used to portray the person in power
- 5-8. In a formal group picture, attention must not be drawn to any one individual in the photograph. However, in an informal group photograph, attention should be drawn toward the most senior member of the group.
1. True
 2. False

- 5-9. You are taking a formal group photograph of eight people. You should arrange them in a total of how many rows?
1. One
 2. Two
 3. Three
 4. Four
- 5-10. You are making a formal group picture of an admiral's staff. The staff consists of the admiral, three captains, seven commanders, two lieutenants, and three CPOs. The admiral should be placed in what location for the picture?
1. On the far right end of the first row
 2. In the center of the back row
 3. In the center of the middle row
 4. In the center of the first row
- 5-11. Which of the following elements of a group photograph is the most difficult to control?
1. The viewpoint
 2. The composition
 3. The people
 4. The distracting background
- 5-12. To take action photographs successfully, you should perform which of the following actions?
1. Anticipate the action
 2. Know the photographic equipment being used
 3. Learn something about the action
 4. All of the above
- 5-13. Action should always be photographed at what time?
1. At the peak
 2. Directly after the peak
 3. Immediately before the peak
- 5-14. You are photographing the Secretary of the Navy presenting a Purple-Heart Medal to an Airman Recruit. Your battle group flag officer and your CO are also involved in the award ceremony. What person should you concentrate on as the center of interest?
1. Secretary of the Navy
 2. Admiral
 3. Commanding Officer
 4. Airman Recruit
-
- Learning Objective: Recognize basic principles of caption writing.
-
- 5-15. Which of the following elements is NOT a basic requirement in caption writing?
1. Explanation
 2. Identification
 3. Credit line
 4. Background information
- 5-16. In a picture caption, what sentence is most important?
1. First
 2. Middle
 3. Last
 4. Closing
- 5-17. When you are writing captions, they should always be written in what (a) voice and (b) tense?
1. (a) Passive (b) past
 2. (a) Active (b) past
 3. (a) Passive (b) present
 4. (a) Active (b) present
- 5-18. The amount of background information included in a caption is determined primarily by which of the following factors?
1. The way the final picture is to be used
 2. The location in which the final picture is to be used
 3. Both 1 and 2 above
 4. The ethnic background of the subject

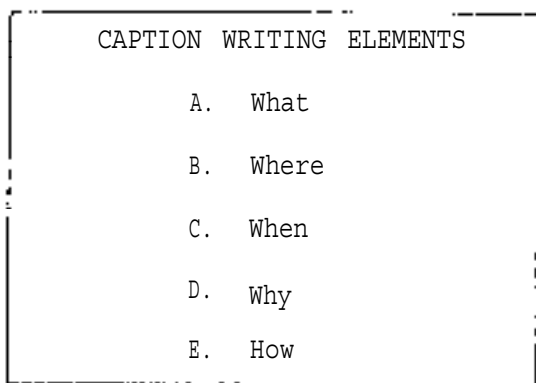

Figure 5A

IN ANSWERING QUESTIONS 5-19 THROUGH 5-22, SELECT THE CAPTION WRITING ELEMENT THAT BEST APPLIES TO THE STATEMENT USED AS THE QUESTION.

5-19. Testing squadron readiness:

1. A
2. B
3. D
4. E

5-20. During July and September:

1. E
2. C
3. B
4. A

5-21. Falling in for muster:

1. A
2. B
3. C
4. D

5-22. On board the USS *Lincoln*:

1. D
2. C
3. B
4. A

5-23. When following the general guidelines for caption writing, you should limit the words to what number?

1. 12
2. 25
3. 50
4. 100

5-24. What element is the most important part of caption writing?

1. Explaining the action
2. Caption length
3. Identifying principal subjects
4. Credit line

5-25. Of the four methods of identifying persons in writing a caption, what method is best?

1. Obvious contrast
2. Elimination
3. From the left
4. Action

5-26. What is the least desirable method of identification used in caption writing?

1. From the left
2. Elimination
3. Obvious contrast
4. Action

Learning Objective: Recognize methods used for investigative photography.

5-27. When photographing a scene as part of an investigation, you should always include which of the following items?

1. The investigative team
2. An overall shot of the scene
3. Close-up photographs of each object in the scene
4. Fingerprints

5-28. You are assigned to take photographs for an investigation. You trip accidentally and knock over several items. Which of the following actions should you take?

1. Photograph the items as they now appear
2. Rearrange the objects as they were and then photograph them
3. Inform the investigative team of your accidental act
4. Say nothing unless asked

5-29. Using color film to photograph the scene of a fire has what primary advantage over black-and-white film?

1. It can be processed faster
2. It records finer detail
3. It can assist in identifying the types of materials being burned
4. It records blackened and charred objects better

5-30. You are taking photographs of a burned-out building. Your basic flash exposure indicates an exposure of f/11. Which of the following aperture settings should you use?

1. f/16
2. f/11
3. f/8
4. f/5.6

5-31. What is the primary purpose of aircraft-accident photography?

1. To identify the person(s) at fault
2. To prevent future accidents
3. To establish the primary cause of the accident
4. To provide photographs for safety grams

5-32. What type of information is NOT required on photographs of an aircraft accident?

1. Type of aircraft
2. Date of accident
3. Name of pilot(s)
4. Type of accident

Learning Objective: Select equipment and methods used in product photography.

5-33. When used properly, which of the following cameras provides the best results when you are photographing small parts in a studio?

1. 35mm SLR
2. Medium-format SLR
3. Medium-format TLR
4. 4x5 view

5-34. The most effective main light for product photography is provided by which of the following light sources?

1. Spotlight
2. Floodlight
3. Fluorescent bulbs
4. Plane reflectors

5-35. In product photography, where is the main light generally located?

1. High and in front of the subject
2. Below and to the side of the subject
3. High and behind the subject
4. Directly above the subject

5-36. In product photography, the subject should appear as though it is illuminated by what number of light source(s)?

1. One
2. Two
3. Three
4. Four

5-37. In the studio, which of the following types of lighting can be used to simulate the light from an overcast sky?

1. Spot
2. Tent
3. Key
4. Flood

- 5-38. When establishing the lighting for a product, you should view the subject from what position?
1. The main light
 2. The fill light
 3. Above the subject
 4. The camera
- 5-39. What type of lighting is used to emphasize the texture of a product?
1. Tent
 2. Fill
 3. Cross
 4. 45 degree
- 5-40. You are using color film for product photography. The areas between the highlights and shadows where you want to record detail should not exceed what number of f/stops?
1. Seven
 2. Six
 3. Five
 4. Four
- 5-41. Your light meter indicates an exposure of 7 seconds at f/8. What is your exposure using the painted light technique?
1. 7 seconds at f/8
 2. 14 seconds at f/4
 3. 14 seconds at f/8
 4. 21 seconds at f/8
- 5-42. When using the painted-light technique, you should use what minimum exposure time?
1. 5 seconds
 2. 10 seconds
 3. 20 seconds
 4. 25 seconds
- 5-43. You are using a mirror to photograph a broken fitting in the wheel well of an aircraft. The broken fitting-to-camera distance is 27 inches, the mirror-to-fitting distance is 19 inches, and the camera-to-mirror distance is 33 inches. What focusing distance, in inches, should you set on the camera lens?
1. 79
 2. 60
 3. 52
 4. 46
- 5-44. You are photographing an arrangement of glassware in the studio using color negative film. Your light-meter reading taken from the background indicates an exposure of 4 seconds at f/16. While at f/16, you should use which of the following camera settings to expose the film?
1. 16 seconds
 2. 12 seconds
 3. 8 seconds
 4. 4 seconds
- 5-45. You are photographing an object in the studio and are using a continuous-tone film (ISO 100) and a high-contrast film (ISO 8) to eliminate an unwanted background. Your exposure for the continuous-tone film is 24 seconds at f/16. What f/stop should you use to expose the slow, high-contrast film?
1. f/16
 2. f/11
 3. f/8
 4. f/5.6

Learning Objective: Recognize equipment and techniques used for photographing buildings and structures.

5-46. What type of camera is best suited for photographing architectural structures?

1. 35mm SLR
2. Medium-format TLR
3. Medium-format SLR
4. View camera

5-47. You are tasked to photograph a new Navy Lodge on board a local NAS. Which of the following weather conditions should you avoid when taking this photograph?

1. Bright day with clear skies
2. Slightly overcast day
3. Cloudy day
4. Bright day with large, puffy clouds

5-48. You are tasked to photograph the interior of a building that has a number of large windows. What time of day should you make the exposures?

1. Early Morning
2. Mid Morning
3. Noon
4. After dark

5-49. A lens shade should always be used over camera lenses.

1. True
2. False

Learning Objective: Identify basic principles used in intelligence-gathering photography.

5-50. What black-and-white film is best suited for taking intelligence-gathering pictures?

1. Kodak Tri-X
2. Kodak Tech Pan
3. Ilford XP-1
4. Kodak Plus-X

5-51. What color film is best suited for taking intelligence-gathering pictures?

1. Kodak Gold
2. Kodak Ektar
3. 3M HR
4. Kodak Vericolor Professional

5-52. Because the resolution of videotape is inferior to film, it should not be used for intelligence-gathering purposes.

1. True
2. False

5-53. What type of shot is most helpful to analysts in determining the overall dimensions of a ship?

1. Starboard beam
2. Stern
3. Port quarter
4. Bow

5-54. Which of the following light-meter reading techniques should you use to photograph an aircraft that is airborne?

1. Integrated
2. Brightest object
3. Incident
4. Substitution

5-55. Intelligence photographs of foreign ports are seldom taken from Navy ships because an ample supply of these images are provided by satellites.

1. True
2. False

ASSIGNMENT 6

Textbook Assignment: "Portraiture." Pages 7-1 through 7-20.

Learning Objective: Identify proper equipment and techniques used in photographing portraits.

6-1. A portrait should emphasize which of the following aspects about a person?

1. Their environment
2. A recognizable likeness only
3. Their personality
4. Their flattering characteristics only

6-2. Which of the following factors can help you succeed in portrait photography?

1. An understanding of the techniques involved
2. An artistic ability
3. The ability to direct subjects
4. All of the above

6-3. What is/are the most important feature(s) of the face?

1. Nose
2. Eyes
3. Mouth
4. Ears

6-4. What is/are the most expressive feature(s) of a face?

1. Eyes
2. Mouth
3. Cheeks
4. Forehead

6-5. You are using a camera that produces a 6x7 cm negative to shoot a head-and-shoulders portrait. Which of the following lenses should you use?

1. 50mm
2. 75mm
3. 150mm
4. 250mm

6-6. What type of background is best suited for official Navy portraits?

1. Bright colored
2. Light, neutral colored
3. Dark colored
4. Glossy surfaced

6-7. Your studio is set up with a brightly colored background and you are shooting color film for a portrait session. What is/are the disadvantage(s) of using this colored background?

1. It can distract from the subject
2. Reflected light may affect the tone of the subject's face
3. It may alter the mood you want to represent
4. Each of the above

6-8. As a minimum, what two colors of backgrounds available should a Navy portrait studio have?

1. White and gray
2. Black and gray
3. Black and white
4. Gray and black

Learning Objective: Select various lighting sources and accessories used in portrait photography.

- 6-9. What light source is best for portrait photography?
1. Sunlight
 2. Daylight
 3. Incandescent light
 4. Electronic flash
- 6-10. You want to produce deep, well-defined shadows on the face of a portrait. What type of light source should you use?
1. Reflected light
 2. Spotlight
 3. Floodlight
 4. Diffused light
- 6-11. The technique that allows only the softer, outer part of a light beam to fall on the subject is known by what term?
1. Diffusing
 2. Snooting
 3. Feathering
 4. Spotting
- 6-12. Which of the following lighting accessories is used to soften specular light?
1. Fresnel lens
 2. Barn door
 3. Snoot
 4. Diffusers
- 6-13. What lighting accessory is used to feather light?
1. Snoot
 2. Barn door
 3. Diffuser
 4. Umbrella
- 6-14. What lighting accessory is used to control spill light?
1. Barn door
 2. Diffuser
 3. Umbrella
 4. Reflector
- 6-15. What lighting accessory is used to control the size of the light beam falling on the subject?
1. Barn door
 2. Snoot
 3. Diffuser
 4. Umbrella
- 6-16. What lighting accessory is used to spread light over a larger area than that provided from the original source?
1. Barn door
 2. Snoot
 3. Diffuser
 4. Umbrella
-
- Learning Objective: Identify camera- and subject-handling techniques used in portrait photography.
-
- 6-17. What type of black-and-white film should you use to emphasize the texture of a man's skin in a portrait?
1. Panchromatic
 2. Colorblind
 3. Orthochromatic
 4. Infrared
- 6-18. Which of the following f/stops is generally better suited for taking portraits?
1. f/8
 2. f/16
 3. f/32
 4. f/64
- 6-19. Portrait appointments should be scheduled no closer than how many minutes apart?
1. 5
 2. 10
 3. 15
 4. 20

- 6-20. People should generally have their portraits taken during what part of the day?
1. Morning
 2. Afternoon
 3. Evening
 4. Night
- 6-21. Which of the following methods helps to provide a natural expression of the subject?
1. Tell them to "just act natural"
 2. Show them an example of how you want them to look
 3. Carry on a conversation with the subject to help them feel at ease
 4. Tell a joke at the time of exposure
- 6-22. When directing the subject for a portrait pose, you, as the photographer, should be in what location?
1. Behind the camera
 2. At the subject's side
 3. Behind the subject
 4. In front of the camera within the circle of light
- 6-23. What is the best average height of a camera for a head-and-shoulders portrait?
1. Chest level
 2. Slightly above the subject's eyes
 3. Slightly below the subject's chin
 4. Nose level
- 6-24. When shooting a full-length portrait, you should begin with your camera at what level to the subject?
1. Waist
 2. Chest
 3. Shoulder
 4. Head
- 6-25. You are shooting a portrait and want the subject to appear to be looking, but not staring at the viewer in the finished print. To create this effect, you should have the subject look in what direction during the camera exposure?
1. Into the camera lens
 2. Slightly above the camera lens
 3. Below the camera lens
 4. At the modeling light
- 6-26. To create the feeling of motion in a head-and-shoulders portrait, you should have the subject sit in what position in relation to the camera?
1. At an angle and leaning slightly forward
 2. At an angle and leaning slightly backward
 3. Square and leaning slightly forward
 4. Square and leaning slightly backward
- 6-27. What is the point of interest in a military portrait?
1. The national ensign
 2. The subject's rank or rating insignia
 3. The subject's awards
 4. The subject's face
-
- Learning Objective: Recognize different types of portrait lighting and their corresponding effects.
-

<p>PORTRAIT LIGHTING</p> <p>A. Rembrandt</p> <p>B. Short</p> <p>C. Broad</p> <p>D. Rim</p>
--

Figure 6A

IN ANSWERING QUESTIONS 6-28 THROUGH 6-31, REFER TO FIGURE 6A AND SELECT THE TYPE OF PORTRAIT LIGHTING USED TO CREATE THE EFFECT USED AS THE QUESTION.

6-28. The side of the face away from the camera is fully lighted:

1. A
2. B
3. C
4. D

6-29. The side of the face away from the camera is lighted by a high main light:

1. A
2. B
3. C
4. D

6-30. The entire face is in shadow:

1. A
2. B
3. C
4. D

6-31. The side of the face toward the camera is well-lighted:

1. A
2. B
3. C
4. D

6-32. What type of lighting produces a shadow directly under the nose?

1. Broad
2. Butterfly
3. Short
4. Rembrandt

6-33. What type of lighting is used to illuminate one side of the face while placing the opposite side completely in shadow?

1. Rim
2. Short
3. Split
4. Broad

Learning Objective: Identify methods used to determine the placement of portrait lights.

6-34. What light source in a portrait-lighting situation is the most influential?

1. Fill
2. Hair
3. Background
4. Modeling

6-35. In military portraits, what type of lighting is used for subjects with a normal shape face?

1. Short
2. Broad
3. Butterfly
4. Spit

6-36. What type of lighting should you use for a subject with a narrow face?

1. Short
2. Broad
3. Spit
4. Rembrandt

6-37. Which of the following lighting effects causes too much light to be reflected from the subject's forehead in a portrait?

1. The fill light is too bright
2. The main light is too far from the fill light
3. The main light is too close to the subject
4. The intensity of the fill light is greater than the main light

- 6-38. What light creates the facial highlights in portrait lighting?
1. Background
 2. Hair
 3. Fill
 4. Main
- 6-39. What factors are used to determine the required direction of the main light in three-quarter portrait lighting?
1. The distance of the main light from the fill light
 2. The size and shape of the subject's nose
 3. The size and intensity of the main light as compared to the fill light
 4. The relationship of the nose shadow to the upper lip
- 6-40. What facial highlight is used to determine the distance of the main light?
1. Nose
 2. Forehead
 3. Chin
 4. Cheek
- 6-41. When naval officers have their portrait made with their cover on, the shadow cast by the visor must not fall across their eyes.
1. True
 2. False
- 6-42. What is the purpose of the fill light in portrait lighting?
1. To provide shadow detail
 2. To increase the level of illumination necessary to obtain greater depth of field
 3. To provide modeling and highlight contrast
 4. To increase the lighting ratio
- 6-43. In three-quarter portrait lighting, the fill light should be in what location?
1. Directly behind the main light
 2. On the same side of the camera as the main light
 3. On the opposite side of the camera from the main light
 4. Behind the subject
- 6-44. The shadow cast under the subject's chin by the fill light helps to separate the head from the neck in portrait lighting, and therefore should be quite dark.
1. True
 2. False
- 6-45. In a portrait subject's eye, what is the small reflection caused by the main light called?
1. Highlight
 2. Star light
 3. Bright light
 4. Catch light
- 6-46. What number of catch lights should be in each eye?
1. One
 2. Two
 3. Three
 4. Four
- 6-47. In broad lighting, the catch light should be in what approximate position?
1. One o'clock
 2. Six o'clock
 3. Three o'clock
 4. Eleven o'clock
- 6-48. In short lighting, the catch light should be in what approximate position?
1. One o'clock
 2. Six o'clock
 3. Three o'clock
 4. Eleven o'clock

- 6-49. What is the maximum lighting ratio for color portraits?
1. 1:1
 2. 2:1
 3. 3:1
 4. 5:1
- 6-50. In portrait lighting, what light is used to provide tonal separation between the subject and the background?
1. Main
 2. Catch
 3. Fill
 4. Background
- 6-51. You are shooting a color portrait for a command roster board. To reproduce the background in its true color, you should ensure what amount of incident light is falling on it?
1. The same as the subject
 2. Twice as much as the subject
 3. One half as much as the subject
 4. Four times as much as the subject
- 6-52. You position the background light so the illumination falls off gradually into the corners of the frame. This produces what effect?
1. It hides uneven borders
 2. It provides image balance
 3. It "locks" the image into the frame
 4. It helps direct attention to the subject's face
- 6-53. Light-meter readings for portraits should be taken with the hair light turned off.
1. True
 2. False
- 6-54. When setting up a portrait using side lighting, you should start with the main light in what position?
1. Very close to the lens axis
 2. 45 degrees from the lens axis
 3. 90 degrees from the lens axis
 4. 180 degrees from the lens axis
- 6-55. What type of portrait lighting should you use to subdue lines and wrinkles in the subject's face?
1. Spit
 2. Broad
 3. Butterfly
 4. Rembrandt
- 6-56. What facial shadow should you use to determine the height of the main light for butterfly lighting?
1. Eyebrow
 2. Nose
 3. Lip
 4. Chin
- 6-57. You are taking a portrait of a female admiral using butterfly lighting. In what position should you place the fill-in light?
1. Close to the lens axis and on the opposite side from the main light
 2. 45 degrees from the lens axis and on the same side as the main light
 3. 45 degrees from the lens axis and on the opposite side of the main light
 4. Directly below the main light and close to the lens axis
-
- Learning Objective: Identify the basic setup used for taking full-length portraits.
-

- 6-58. What background color is best suited for a full-length portrait of an officer wearing khakis?
1. Gray
 2. Light blue
 3. Beige
 4. White
- 6-59. You are taking a full-length officer promotion portrait of a CDR. You should pose the subject in what manner?
1. Square to the camera
 2. Facing your left
 3. Three quarters with the left shoulder forward
 4. One that makes him appear thin
- 6-60. Because all military portraits are standardized, they should be taken with the same pose, camera height, and lighting setup.
1. True
 2. False

Learning Objective: Identify corrective techniques used in portrait photography.

PORTRAIT PROBLEM AREAS

- A. Protruding lips
- B. Glasses
- C. Baldness
- D. Fat, round face
- E. Deep-set eyes
- F. Wide forehead

Figure 6B

IN ANSWERING QUESTIONS 6-61 THROUGH 6-66, REFER TO FIGURE 6B AND SELECT THE PORTRAIT PROBLEM AREA THAT BEST MATCHES THE CORRECTIVE ACTION USED AS THE QUESTION.

- 6-61. Low-camera viewpoint and front-lighting:
1. B
 2. C
 3. D
 4. E
- 6-62. Shoot three-quarter view. Short or sidelighting:
1. A
 2. C
 3. D
 4. F
- 6-63. Low main light:
1. A
 2. B
 3. D
 4. F
- 6-64. Low-camera viewpoint. Light to blend head with background:
1. B
 2. C
 3. D
 4. F
- 6-65. High, three-quarter or front-lighting. Tilt head downward:
1. A
 2. B
 3. C
 4. E
- 6-66. Low-camera viewpoint. Tilt chin upward:
1. A
 2. B
 3. D
 4. F
- 6-67. Film exposure for portraits should be based on the intensity of
1. the fill light only
 2. the main light only
 3. the fill and main lights only
 4. all lights used

Learning Objective: Recognize principles used for taking passport photographs.

- 6-68. All active-duty military personnel are entitled to no cost tourist passport photographs taken in Navy imaging facilities.
1. True
 2. False
- 6-69. The head size for passport photographs must be what size, in inches?
1. 1 to 1 3/8
 2. 1/2 to 1
 3. 3/4 to 1 1/4
 4. 1 3/8 to 2
- 6-70. A Navy lieutenant enters your imaging facility for a passport photograph wearing prescription aviator sunglasses. He normally wears glasses but does not have glaucoma. Which of the following actions should you take?
1. Ask him to put on his regular glasses and then take the photograph
 2. Have him remove the sunglasses and take the photograph
 3. Say nothing and take the photograph with the sunglasses on

ASSIGNMENT 7

Textbook Assignment: "Copying" and "Chemical Mixing." Pages 8-1 through 9-12.

Learning Objective: Recognize different types of copy originals.

COPY TERMS

- A. Line Originals
- B. Reproduction
- C. Halftone
- D. Continuous-Tone Original
- E. Duplication

Figure 7A

IN ANSWERING QUESTIONS 7-1 THROUGH 7-4, SELECT THE COPY TERM THAT BEST APPLIES TO THE DEFINITION USED AS THE QUESTION.

7-1. A photograph comprised of many different gray, white, and black tones:

- 1. A
- 2. B
- 3. D
- 4. E

7-2. The product of copying:

- 1. A
- 2. B
- 3. C
- 4. D

7-3. A black-and-white printed page:

- 1. A
- 2. B
- 3. C
- 4. D

7-4. A picture made of various size dots:

- 1. A
- 2. B
- 3. C
- 4. D

Learning Objective: Identify conditions of copyrighted materials.

7-5. Copyright laws apply only to works published and made available for sale.

- 1. True
- 2. False

7-6. To play it safe as a Navy Photographer's Mate, you should abide by which of the following rules regarding copyright information?

- 1. Never copy information that is copyrighted
- 2. You may copy any copyrighted material if it will be used one time only and the copy is marked "For Official Use Only"
- 3. Be sure permission from the copyright holder is obtained before copying copyrighted materials
- 4. If it is used for training purposes, it may be copied

7-7. Which of the following items may be copyrighted?

- 1. Compact disks
- 2. Videotapes
- 3. Photographs
- 4. Each of the above

- 7-8. At what point in time does a photograph legally become copyrighted?
1. When it is processed
 2. When it is submitted to the Copyright Office
 3. When it is published
 4. When it is sold
- 7-9. Which of the following statements regarding copyright is true?
1. A notice of copyright is marked conspicuously on all copyrighted documents
 2. Although a publication does not carry a notice of copyright, it may still be copyrighted
 3. Without permission from the copyright owner, you may still copy publications from foreign countries
 4. All of the above
- 7-10. A literary work was created by two authors in 1980. Neither of the authors worked for hire. The first author died in 1981, and the second author died in 1885. What year does the copyright expire for this work?
1. 2031
 2. 2035
 3. 2056
 4. 2085
- 7-11. What, if anything, is meant by "international copyright?"
1. The material is copyrighted throughout the world
 2. The copyright applies to UCC countries only
 3. All UCC countries have agreed to copyright the material
 4. There is no such thing as "international copyright"
- 7-12. A Navy pilot takes some air-to-air photographs of an aircraft just introduced to the fleet. As assistant PAO, this is a part of his duty. These photographs are copyright protected for what length of time, if any?
1. 50 years after his death
 2. 75 years after his death
 3. 100 years from the date the photographs were processed
 4. None
- 7-13. Which of the following statements concerning copyright information and the principle of "fair use" is NOT true?
1. For educational purposes, a teacher can make a single copy of a document for each student and use the copies from year to year
 2. A single copy of an article from a magazine may be used for research purposes
 3. There is no limit to the number of copies that can be made of a table of weights and measures
 4. A teacher may make a single copy of a chapter in a book if the material is used in preparation for teaching a class
- 7-14. What instruction provides information on the use of copyrighted material for official Navy use?
1. OPNAVINST 5290.1
 2. SECNAVINST 5870.5
 3. SECNAVINST 5216.5
 4. COPYRITINST 10700.3

7-15. You are standing "duty PH" alone at a base imaging facility. The CO of the base personally brings in a copyrighted document that he needs copied to a 35mm slide at once. What action should you take?

1. Tell the CO you cannot copy the document because it is copyrighted
2. Mask the copyright notice, then copy the document
3. Ensure the CO knows that the document is copyrighted before you begin the job
4. Make an extra slide of the document and forward it to the CNO

7-16. It is illegal to photograph United States currency.

1. True
2. False

Learning Objective: Recognize equipment, film, and lighting techniques used for photographic copying.

7-17. For an imaging facility that performs a large quantity of copy work, what focusing system is best?

1. SLR
2. Rangefinder
3. Ground glass
4. Split level

7-18. What is the minimum desired bellows extension for a copy camera?

1. The lens focal length
2. Twice the lens focal length
3. Three times the lens focal length
4. Four times the lens focal length

7-19. What type of lens is designed specifically for copying?

1. Process
2. Convertible
3. High resolve
- Two dimensional

7-20. What primary factor determines the focal-length lens you should use for copy work?

1. The lens-to-original distance
2. The size of the original
3. The distance from the light source to the original
4. The size of the negative

7-21. For copy work, you should use which of the following lenses, in inches, on a camera that produces an 8x10-inch negative?

1. 8
2. 10
3. 12
4. 18

7-22. The copyboard of a copy camera should not be white or a light color for which of the following reasons?

1. The film will be overexposed
2. The film will be underexposed
3. The reproduced image will lack good contrast
4. The reproduced image will have excessive contrast

7-23. What is the color temperature rating of tungsten lamps?

1. 3200 K and 3400 K
2. 5400 K and 7200 K
3. 7400 K and 9600 K
4. 10,000 K and 21,000 K

7-24. What is the approximate lifetime, in hours, of a 3400 K lamp?

1. 5
2. 9
3. 3
4. 34

7-25. What type of light source is best suited for copying a painting with rough surface?

1. 3200 K tungsten lamp
2. Fluorescent lamp
3. Electronic flash
4. Quartz-halogen lamp

- 7-26. You are copying charts to 35mm color slides on an MP-4 copy camera. The right-rear lamp burns out. What lamp(s) should you replace?
1. The right-rear lamp only
 2. The right-rear and the right-front lamps only
 3. The right-rear and the left-rear lamps only
 4. All four lamps
- 7-27. What type of film should you use to copy a black-and-white line original?
1. Kodalith
 2. Plus-X
 3. HP5 Plus
 4. XP2
- 7-28. Which, if any, of the following types of film should you use to make a black-and-white copy of a colored line original?
1. Colorblind
 2. Orthochromatic
 3. Panchromatic
 4. None of the above
- 7-29. To copy a black-and-white continuous-tone original, you should use which of the following films??
1. Kodalith
 2. Contrast Process Pan
 3. Kodak Commercial
 4. Tri-X
- 7-30. Which of the following films should you use to produce a color negative of a color photographic print?
1. Vericolor III Professional
 2. Kodak Internegative
 3. Ektachrome
 4. Kodacolor
- 7-31. You are printing a number of color prints that will later be copied to color slides. What surface paper should you use to make the prints?
1. Glossy
 2. Matte
 3. Semimatte
 4. Pearl
- 7-32. At what angle to the original should the copy lights be positioned for general, routine copy work?
1. 90°
 2. 45°
 3. 30°
 4. 10°
- 7-33. You have produced a copy negative that you know was lighted evenly, but the negative still has less density at the edges than at the center. What factor most probably caused this problem?
1. A wide-angle lens was used
 2. A telephoto lens was used
 3. The film was overexposed
 4. The film was underexposed
- 7-34. What type of film requires the most critical exposure?
1. High contrast
 2. Moderate contrast
 3. Normal contrast
 4. Low contrast
- 7-35. Many bright reflections are occurring from high points of brush strokes on an oil painting that you are copying. What may be the end result?
1. Increased contrast
 2. Reduced contrast
 3. Underexposure
 4. Overexposure

- 7-36. Polarizing screens are being used over copy lights. Approximately how much of an increase in exposure is required as compared to using the lights unscreened?
1. 5 times
 2. 2 times
 3. 12 times
 4. 20 times
- 7-37. You are using an ISO 100 speed film to make copies. Your exposure meter reading is taken from an 18-percent gray card. What ISO speed should you set into the meter?
1. 25
 2. 50
 3. 100
 4. 200
- 7-38. You are producing copies using a 14-inch bellows extension. The lens focal length is 6 inches and the indicated exposure is 3 seconds. What exposure time, in seconds, should you use?
1. 6
 2. 12
 3. 16
 4. 32
- 7-39. When photographing images of a CRT, you must be aware of which of the following requirements?
1. The shutter speed is extremely critical when photographing radarscopes
 2. The screen brightness must be adjusted to maximum so the brightest possible images are provided
 3. To shoot a computer monitor, you must set the camera shutter speed to 1/250 second
 4. The optical axis of the lens must be centered and perpendicular to the monitor
- 7-40. For slide duplication, what side of the film should face the camera?
1. Emulsion
 2. Base
- 7-41. You have copied a number of slides and all of the processed images on the roll are extremely yellow. What action should you take first?
1. Subtract 50Y from the filter pack
 2. Add 50B to the filter pack
 3. Add 50M and 50C to the filter pack
 4. Check the duplicating system to ensure the CC filters were in the proper position when the slides were exposed
- 7-42. When trying to determine the color correction necessary for a duplicate color slide, you should examine what tones?
1. Midtones
 2. Shadows
 3. Highlights
- 7-43. By viewing a color slide through a CC10R filter, you determined that the color looks correct. Which of the following adjustments should you make to your filter pack?
1. Subtract CC10R only
 2. Subtract CC10M and CC10Y
 3. Add CC10C only
 4. Subtract CC10C only

Learning Objective: Identify methods used to duplicate slides.

Learning Objective: Identify proper mixing and storage procedures for photographic chemicals.

7-44. What is the most important reason for ensuring that photographic chemicals are mixed properly?

1. using improperly mixed chemicals is always hazardous to the user's health
2. Improperly mixed chemicals may ruin the film from an important mission
3. The mixing equipment may be damaged

7-45. The storage of unmixed chemicals should be at what approximate temperature and relative humidity, respectively?

1. 20°F; 68 percent
2. 40°F; 75 percent
3. 68°F; 20 percent
4. 75°F; 40 percent

7-46. Containers made from what material are best for storing liquid developer?

1. Hard rubber
2. Plastic
3. Glass
4. Stainless steel

7-47. Air space should never be left in a large bottle used for storing developer replenisher.

1. True
2. False

7-48. Floating lids are used for storage of large volumes of solution in tanks for what primary purpose?

1. To prevent dust from settling on the surface of the solution
2. To prevent water in the solution from evaporating
3. To prevent unauthorized use of the solution
4. To protect the solution from aerial oxidation

7-49. Which of the following materials is NOT suitable for a photographic chemical storage tank?

1. Aluminum
2. Glass
3. 316 Stainless Steel
4. Polyethylene

7-50. When washed well between uses, wooden paddles make excellent chemical mixing tools.

1. True
2. False

7-51. The curved surface at the top of a solution is known by what term?

1. Convexation
2. Concavation
3. Meniscus
4. Mantissa

7-52. An increase in temperature has what effect, if any, on chemical action?

1. It increases
2. It decreases
3. None

Learning Objective: Identify items of equipment used in Navy imaging facilities to test or verify chemical solutions.

7-53. What instrument is used to measure the specific gravity of a solution?

1. Densitometer
2. pH meter
3. Hydrometer
4. Thermometer

- 7-54. The specific gravity measurement of a solution is below the lower limit. This may be an indication of which of the following errors?
1. The solution is diluted with too much water
 2. Not enough water was added
 3. Too much of an ingredient has been added
 4. The solution may be highly acidic
- 7-55. A hydrometer used to measure the silver content of a fixing bath is calibrated in grams of silver per
1. ounce
 2. milliliter
 3. gallon
 4. liter
- 7-56. Specific gravity is a measurement of what property of a liquid?
1. Composition
 2. Strength
 3. Opacity
 4. Density
- 7-57. What part of the meniscus, if any, at the stem of the hydrometer indicates the ratio of the density of a solution to the density of distilled water?
1. The top
 2. The center
 3. The bottom
 4. None
- 7-58. Acidity and alkalinity of solutions are measured with what instrument?
1. Hydrometer
 2. pH meter
 3. Activity indicator
 4. Sensitometer
- 7-59. Photographic developing solutions have which of the following pH values?
1. 3.1 to 5.0
 2. 5.0 to 8.0
 3. 8.0 to 12.0
 4. 12.0 to 14.0
- 7-60. An alkali may have which of the following pH values?
1. 1.0
 2. 5.0
 3. 7.0
 4. 9.0
- 7-61. A pH value of 7.0 is
1. acidic
 2. alkaline
 3. neutral
- 7-62. A pH value of 1.0 is how many times stronger than a pH value of 3.0?
1. One
 2. Two
 3. Ten
 4. One hundred
- 7-63. The solution used to standardize a pH meter is known as what type of solution?
1. Acid
 2. Alkali
 3. Buffer
 4. Neutral
- 7-64. You are standardizing a pH meter before taking the pH reading of a black-and-white fixer. You should use a buffer solution with what pH value to standardize the meter?
1. 14.0
 2. 10.0
 3. 7.0
 4. 4.0
-
- Learning Objective: Identify procedures used in mixing photographic chemicals.
-

7-65. You have set up an impeller type of mixer to mix a developer solution, but you have adjusted the clamp improperly so the shaft is vertical and in the center of the container. What is the most probable end result?

1. The motor bearings are damaged
2. Too much air was whipped into the solution
3. The mixer vibrated enough to mix the chemicals sufficiently
4. The solution was churned from top to bottom, rather than from bottom to top

7-66. How many degrees Celsius equate to 68°F?

1. 10°C
2. 20°C
3. 30°C
4. 40°C

7-67. You are mixing a developing solution and the directions call for water at 23.8°C. This is equal to how many degrees Fahrenheit?

1. 18.75°F
2. 37.50°F
3. 75.00°F
4. 125.50°F

7-68. You are preparing a working solution of developer from a stock solution. The instructions call for 1 part of stock solution and 3 parts water. You need a total of 1 gallon of working solution. What amount of water, in ounces, should you add to the solution?

1. 32
2. 64
3. 96
4. 128

7-69. For adequate ventilation in a chemical mixing area, there should be one complete air change every

1. 15 minutes
2. 30 minutes
3. 3 minutes
4. 45 minutes

7-70. It is permissible to mix photographic chemicals in a photographic print room that has adequate ventilation.

1. True
2. False

7-71. You need 32 ounces of developer solution. The only size package of dry, prepackaged chemicals you have on hand makes 128 ounces. Should you mix the entire package to make 128 ounces and, if so, why?

1. Yes; when only part of the package is mixed, some of the ingredients may be left out of the resulting solution
2. Yes; when only part of the package is mixed, the resulting solution will not develop film
3. No; dry, packaged chemicals are homogenized
4. No; dry, packaged chemicals are formulated to be mixed either in part or in whole

7-72. You should follow what procedure when mixing chemicals?

1. Add water to dry chemicals and acid to water
2. Add dry chemicals to water and acid to water
3. Add water to dry chemicals and water to acid
4. Add dry chemicals to water and water to acid

Learning Objective: Recognize safety precautions required in chemical mixing areas.

7-73. Labels on chemical storage tanks must include the name of the solution, hazardous chemicals contained, the name of the person who mixed it, and what other information?

1. The water-mixing temperature
2. The date mixed
3. The antidote
4. The name of the chemical-mixing supervisor

- 7-74. What rule(s) is/are important to remember whenever you are working around chemicals?
1. An antidote is for emergency use only
 2. Ingestion of a poisonous chemical may be induced by smoking
 3. A person who has spilled acid on himself should seek medical attention immediately
 4. All of the above
- 7-75. Which of the following personnel must be completely familiar with Material Safety Data Sheets (MSDS)?
1. The division officer only
 2. The division officer and LCPO only
 3. The division officer, LCPO, and production PO only
 4. All persons within an imaging facility

ASSIGNMENT 8

Textbook Assignment: "Image Processing and Control." Pages 10-1 through 10-30.

Learning Objective: Recognize functions of the various solutions used to process light-sensitive materials.

- | | |
|--|--|
| <p>8-1. What process is most commonly used for film development?</p> <ol style="list-style-type: none">1. Physical2. Chemical3. Intensification4. Latent conversion <p>8-2. When performed correctly, the chemical development process reduces exposed silver halides to what composition?</p> <ol style="list-style-type: none">1. Black metallic silver2. Soluble-silver salt3. Dye-image salt4. Gray-tone dye <p>8-3. All silver halides, both exposed and unexposed, can be reduced to metallic silver in the development process.</p> <ol style="list-style-type: none">1. True2. False <p>8-4. What term describes the amount of silver in a film emulsion that has been reduced to black metallic silver?</p> <ol style="list-style-type: none">1. Light struck2. Rate phenomenon3. It prevents the formation of poisonous gas4. It prevents the reducing agent from attacking the unexposed silver halides <p>8-7. Which of the following chemicals may be used as a preservative?</p> <ol style="list-style-type: none">1. Hydroquinone2. Metol3. Sodium hydroxide4. Sodium sulfite <p>8-8. What ingredient in a developing solution makes it alkaline?</p> <ol style="list-style-type: none">1. Reducing agent2. Accelerator3. Preservative4. Restrainer <p>8-9. What two functions does the accelerator in a developing agent serve?</p> <ol style="list-style-type: none">1. It constricts the emulsion and prevents aerial oxidation2. It constricts the emulsion and increases the rate of development3. It swells the emulsion and absorbs the halide elements freed from the silver4. It swells the emulsion and retards the rate of development <p>8-10. A developer with which of the following pH values will most likely produce an image with a finer grain?</p> <ol style="list-style-type: none">1. 1.52. 5.53. 8.54. 11.0 |
|--|--|

- 8-11. The restrainer in a developing solution serves what purpose?
1. It slows down the action of the reducing agent
 2. It prevents the preservative from etching the silver grains
 3. It reduces image contrast
 4. It prevents the solution from oxidizing

- 8-12. Which of the following developer ingredients is used to prevent chemical fog?

1. Metol
2. Hydroquinone
3. Sodium sulfite
4. Potassium bromide

Learning Objective: Identify different types of black-and-white developers and their uses.

- 8-13. In the development stage of film processing, what areas of the negative are converted to black metallic silver first?

1. Highlights
2. Mid-tones
3. Shadows

- 8-14. Which of the following factors does NOT determine the type of developer you choose to process film?

1. Film size
2. Type of process
3. Exposure conditions
4. Type of film

- 8-15. When black-and-white film is processed in a fine-grain developer, the grain structure cannot be seen even in prints made at high magnifications.

1. True
2. False

- 8-16. What type of developer should you use to process a line copy film?

1. High definition
2. Fine grain
3. High contrast
4. General purpose

- 8-17. Which of the following statements is NOT a property of a compensating developer?

1. It increases image sharpness
2. It may produce acceptable negatives that are one or two f/stops underexposed
3. It is recommended for use with fine-grain emulsions only
4. It produces extremely fine grain

- 8-18. What effect, if any, does the by-products caused by the reduction of silver halides have on the pH of a developing solution?

1. It increases
2. It decreases
3. None

- 8-19. Which of the following actions should you take to compensate for the additional bromide present in a used developer?

1. Increase the developing time
2. Decrease the developing time
3. Add more restrainer
4. Lower the temperature of the developer

- 8-20. Which of the following ingredients is NOT included in a developer replenisher?

1. Reducing agent
2. Preservative
3. Restrainer
4. Water

- 8-21. What is the primary reason for using a developer replenisher?
1. To allow use of the same developing solution indefinitely
 2. To maintain the composition of a developer
 3. To extract the used developer
 4. To keep the developer activity constant

- 8-22. What replenishment method is used to maintain solution volume only?

1. Bleed
2. Topping off
3. Titration

- 8-23. The processing characteristics of a developer remains more consistent when what replenishment method is used?

1. Bleed
2. Topping off
3. Titration

Learning Objective: Identify procedures carried out after film is developed.

- 8-24. A water-rinse bath stops the action of the developer.

1. True
2. False

- 8-25. What property of a stop bath prevents further development?

1. Temperature
2. Volume
3. Penetrating action
4. pH

- 8-26. A solution with which of the following pH readings should be used as a stop bath?

1. 2.0
2. 5.0
3. 7.0
4. 9.0

- 8-27. A stop bath should be made up of a weak acid for which of the following reasons?

1. To prevent damage to the film emulsion
2. To prevent the fixing bath from sulphurizing
3. Both 1 and 2 above
4. To prevent darkroom workers from inhaling strong acid fumes

- 8-28. What type of acid is commonly used as a stop bath and in what strength (percentage)?

1. Sulfuric; 28.0%
2. Acetic; 99.5%
3. Sulfuric; 99.5%
4. Acetic; 28.0%

- 8-29. Glacial acetic acid freezes at what temperature, in degrees Fahrenheit?

1. 61°F
2. 32°F
3. 10°F
4. 0°F

- 8-30. For a normal stop bath, you should mix a total of how many ounces of 28 percent acetic acid with 32 ounces of water?

1. 1
2. 1/2
3. 16
4. 28

- 8-31. Once film is treated in a stop bath, it is no longer sensitive to light?

1. True
2. False

- 8-32. What step in film processing makes the silver salts that are not affected by the developer water soluble?

1. Water rinse
2. Stop bath
3. Fixer
4. Wash

- 8-33. Which of the following chemicals is used commonly as a silver-halide solvent?
1. Acetic acid
 2. Sodium thiosulfate
 3. Sodium sulfite
 4. Borax
- 8-34. Which of the following chemicals is added to fixing solutions to prevent sulfurization and discoloration as well as aiding in prevention of stains?
1. Sodium thiosulfate
 2. Ammonium thiosulfate
 3. Sodium sulfite
 4. Potassium alum
- 8-35. Which of the following films requires the longest fixing time?
1. Very fine grain
 2. Fine grain
 3. Medium grain
 4. Coarse grain
- 8-36. You used an undeveloped piece of film to determine the proper fixing time. The film took 2 minutes to clear. After development, what length of time, in minutes, should you fix the same type of film?
1. 1
 2. 2
 3. 8
 4. 4
- 8-37. A fresh fixer used to process black-and-white film takes 4 minutes to clear a piece of undeveloped film. The fixer should be considered exhausted when it takes a total of how many minutes to clear undeveloped film?
1. 5
 2. 6
 3. 7
 4. 8
- 8-38. The purpose of washing film is to remove which of the following elements?
1. Black metallic silver
 2. Fixer
 3. Developer
 4. Silver halides
- 8-39. For black-and-white film, the maximum recommended wash water is what temperature, in degrees Fahrenheit?
1. 65°F
 2. 70°F
 3. 75°F
 4. 80°F
- 8-40. The time required to wash negatives in a large tank is 20 minutes. However, halfway through the wash cycle a PH Striker from the deck department puts his fixer-covered hand into the wash tank. You should wash the negatives what additional amount of time?
1. 5 minutes
 2. 10 minutes
 3. 20 minutes
 4. 30 minutes
- 8-41. The final stage in film processing is what step?
1. Drying
 2. Washing
 3. Fixing
 4. Captioning
- 8-42. Which of the following statements is correct regarding the wetting agent used in film processing?
1. It promotes even drying
 2. It helps wash the film because it is made of a soaplike substance
 3. It retards vigorous drying that causes film curl
 4. It shrinks the swollen gelatin

- 8-43. You place a long roll of 35mm film in a film dryer to dry. What action should you take to prevent the film from curling?
1. Attach a film clip to the bottom of the roll
 2. Cut the film into six-frame segments
 3. Dry the film on the film reel
 4. Hang the film in a U-shape loop

8-44. What is the best "cure" for film-drying problems?

1. Rewashing
2. Retouching
3. Prevention
4. Using a wetting agent

8-45. Film that is overdried can be identified by what characteristic?

1. The film curls toward the emulsion
2. The film curls toward the base
3. The base of the film turns pink
4. The images on the film appear faded

8-46. Film dryers use air impingement for what reason?

1. To help harden the gelatin
2. To cause the metallic silver to "set"
3. To prevent film curl
4. To promote faster drying

Learning Objective: Recognize equipment used in film processing.

8-47. Duckboards used in photographic processing sinks serve what purpose?

1. They rock trays and tanks to provide even agitation
2. They allow water to drain completely
3. They allow tanks or trays to float in the water bath
4. They allow water to circulate under and around tanks and trays to maintain chemical temperatures

8-48. What factor has the greatest bearing on selecting a safelight filter to use with a given photographic material?

1. The wattage of the light bulb
2. The working distance from the safelight to the light-sensitive material
3. The color sensitivity of the light-sensitive material
4. The length of time the light-sensitive material must be exposed to the safelight illumination

8-49. It takes 6 minutes to process a given light-sensitive material. To carry out the entire process of this material under the illumination of a safelight, you must ensure the safelight does NOT cause any evidence of fogging for what minimum length of time, in minutes?

1. 6
2. 8
3. 12
4. 24

8-50. What type of roll film reel is used most commonly in Navy imaging facilities?

1. Thumb-feed plastic
2. Center-feed plastic
3. Thumb-feed stainless steel
4. Center-feed stainless steel

8-51. A total of how many sheets of film can be washed properly at one time in a tray?

1. One
2. Two
3. Three
4. Four

8-52. What is the most effective method of washing film or paper in a tray?

1. Allow the water to fall directly on the film
2. Dump or change the water in the tray every 5 minutes
3. Rock the tray constantly
4. Use a siphon system

8-53. On board ships, a backflow preventer must be installed in the plumbing system when potable water is used to wash negatives and prints with a siphon system.

1. True
2. False

Learning Objective: Recognize procedures used in processing photographic film.

LIGHTING CONDITION
1. Dark
2. White light

Figure 8A

IN ANSWERING QUESTIONS 8-54 THROUGH 8-58, REFER TO FIGURE 8A. SELECT THE LIGHTING CONDITION USED TO CARRY OUT THE PROCESSING STEP USED AS THE QUESTION.

8-54. Fixing:

1. 1
2. 2

8-55. Drying:

1. 1
2. 2

8-56. Washing:

1. 1
2. 2

8-57. Developing:

1. 1
2. 2

8-58. Stop bath:

1. 1
2. 2

8-59. Which of the following factors affect film development?

1. Time
2. Temperature
3. Agitation
4. Each of the above

8-60. Which of the following publications provides complete processing information for all light-sensitive materials used in your imaging facility?

1. *Navy Visual Information Management and Operations Manual*
2. *Manual of Photography*
3. *Photo-Lab-Index*
4. *Kodak Guide to Film Processing*

8-61. For hand processing black-and-white film, you should agitate the film in what manner when (a) tray processing and (b) tank processing.

1. (a) constantly
(b) constantly
2. (a) constantly
(b) intermittently
3. (a) intermittently
(b) intermittently
4. (a) intermittently
(b) constantly

8-62. You are hand processing four rolls of 35mm film in a small tank designed to hold five 35mm reels. What action should you take before processing the film?

1. Place an empty 35mm reel in the bottom of the tank before placing the loaded reels
2. Place an empty 35mm reel on top of the loaded reels in the processing tank
3. Place an empty 35mm reel in the center of the processing tank in between the second and the third loaded reels
4. Process the film leaving empty space in the processing tank

8-63. When processing roll film in the tank-and-reel system, you should dislodge air bubbles from roll film in what manner?

1. Roll the tank along the bottom of the sink
2. Invert the tank several times
3. Shake the tank
4. Bang the tank on the edge of a hard surface

8-64. Which of the following processes is used to process color and some monochrome negative film in Navy imaging facilities?

1. Kodak E-6
2. Kodak Flexicolor
3. Kodak EP-2
4. Kodak RA-4

8-65. You are processing color negatives. During what processing step is temperature the most critical?

1. Color developer
2. Bleach
3. Fixer
4. Stabilizer

8-66. The Kodak E-6 process has what number of chemical steps?

1. Eight
2. Seven
3. Six
4. Four

8-67. You are processing color reversal film in the E-6 process. During what step is your first opportunity to subject the film to white light without fogging the film?

1. Final rinse
2. Fixer
3. Bleach
4. Reversal bath

8-68. You are hand processing a roll of Ektachrome film. The entire roll of film was underexposed by one f/stop. What alteration to the process should you make to compensate for the underexposure?

1. Increase the time in the first developer only
2. Increase the time in the first developer and the color developer only
3. Increase the time in the bleach by 2 minutes only
4. Increase the time of all processing steps by 20 percent

Learning Objective: Identify advantages and disadvantages of machine processing.

8-69. Which of the following advantages apply to photographic machine processors?

1. They can process a high volume of production efficiently
2. They provide more consistent results than hand processing
3. Both 1 and 2 above
4. They require very little maintenance

8-70. Which of the following factors is an advantage of the Image Maker processor?

1. It requires no maintenance
2. Operator error is impossible
3. It is capable of processing a number of different films and papers
4. The chemicals can be easily replenished and used indefinitely

8-71. What factor(s) determine(s) the processing time required on a roller--transport processor?

1. The depth of the processing tanks
2. The distance the film must travel
3. The machine speed
4. All of the above

- 8-72. You should consult which of the following publications for specifications on installing an automatic film processor?
1. The U.S. Navy Standard Installation Manual
 2. The Kodak Processing Standards Manual
 3. The manufacturer's installation and service manual
 4. The Photo-Lab-Index
- 8-73. What unit of measure is used to express film processing time in an automatic roller-transport processing machine?
1. Feet per minute
 2. Time in/out
 3. Rate of travel
 4. Roller rack rotation
- 8-74. The roller assembly in the fixing tank of a roller-transport processor holds 18 feet of film. The machine is operated at 7.5 feet per minute. What is the fixing time, in minutes?
1. 1.8
 2. 2.4
 3. 3.2
 4. 4.1
- 8-75. The film exiting the dryer of an automatic processor is curled excessively. What action should you take?
1. Increase the transport speed
 2. Decrease the transport speed
 3. Increase the dryer temperature
 4. Decrease the dryer temperature

ASSIGNMENT 9

Textbook Assignment: "Image Processing and Control," "Black--and-White Printing," and "Color Printing." Pages 10-31 through 12-17.

Learning Objective: Identify characteristics of high-quality negatives.

9-1. A black-and--white negative should make a good print when printed with what contrast printing filter?

1. No. 1
2. No. 2
3. No. 0
4. No. 4

9-2. What areas have the most density on a negative?

1. Highlights
2. Shadows
3. Midtones

9-3. The difference between the highlight and shadow densities describes what characteristic of a negative?

1. Opacity
2. Tonal gradation
3. Density
4. Contrast

9-4. Which of the following combined factors will produce a thin negative?

1. Underexposure and underdevelopment
2. Underexposure and overdevelopment
3. Overexposure and underdevelopment
4. Overexposure and overdevelopment

9-5. Which of the following areas in a photographed scene will produce the most density on a negative?

1. A shadow
2. A red car
3. A black sailor in winter blues
4. A white road sign

9-6. A processed black-and-white negative has good shadow detail but lacks good contrast and highlight densities. What is the most probable cause of these negative characteristics?

1. Normal exposure and overdevelopment
2. Normal exposure and underdevelopment
3. Underexposure and underdevelopment
4. Underexposure and normal development

9-7. Which of the following factors contribute to the graininess of a negative?

1. The type of emulsion
2. Development
3. Exposure
4. Each of the above

Learning Objective: Recognize equipment and the method used to monitor photographic processes.

9-8. What instrument provides consistent, repeatable exposures and is used to produce test strips?

1. Densitometer
2. Sensitometer
3. Photo sensitizier
4. Grier film exposier

- 9-9. A step tablet provides a range of what number of f/stops?
1. 21
 2. 11
 3. 10
 4. 7
- 9-10. On a 21-step tablet, the difference in density between each step is what number of f/stops?
1. One
 2. Two
 3. One half
 4. One third
- 9-11. What instrument is used to read densities from photographic papers and film?
1. Sensitometer
 2. Densitometer
 3. Emulsion meter
 4. pH meter
- 9-12. You are reading the densities of a Kodacolor test strip. The filter setting should be set to what status?
1. M
 2. K
 3. C
 4. A
- 9-13. When reading a control strip on a densitometer, you should take the readings from (a) what area of the step with (b) the emulsion facing in what direction?
1. (a) Center (b) down
 2. (a) Center (b) up
 4. (a) Edge (b) down
 4. (a) Edge (b) up
- 9-14. On a process control chart, what does the symbol \bar{X} represent?
1. The center line
 2. The mean
 3. The average
 4. Each of the above
- 9-15. You plotted a Kodacolor control strip at the beginning of the production day. The HD reading plotted 0.10 units above the UCL. What action should you take?
1. Process the film normally
 2. Speed up the processor by 10 percent
 3. Add 1000 ml of developer replenisher
 4. Notify your supervisor
-
- Learning Objective: Recognize factors affecting the production and quality of contact black-and-white prints.
-
- 9-16. The most familiar type of photographic print has what type of base?
1. Paper
 2. Film
 3. Resin
 4. Ester
- 9-17. What are the two primary methods of making photographic prints?
1. Positive and negative reproduction
 2. Contact and projection printing
 3. Precision and fallacious reduction
 4. Enlargement and reduction printing
- 9-18. What printing method(s) can be used to produce print images that are the same size as the negative images?
1. Contact
 2. Projection
 3. Both 1 and 2 above
 4. Precision
- 9-19. Variable-contrast photographic papers are not sensitive to which of the following colors of light?
1. Blue
 2. Green
 3. Red
 4. Cyan

9-20. When hand processing black-and-white prints, you should use what minimum number of trays?

1. One
2. Two
3. Three
4. Four

9-21. What number of trays is recommended for hand processing black-and-white prints?

1. Five
2. Seven
3. Three
4. Four

9-22. Contact printing produces what negative to print ratio?

1. 1:1
2. 2:1
3. 1:2
4. 2:2

9-23. What grade of glass should be used when making color contact prints?

1. White
2. Neutral
3. Crystal
4. Clear Al

9-24. When using a proof printer, you should place the emulsion side of (a) paper and (b) film in what direction?

1. (a) Down (b) down
2. (a) Down (b) up
3. (a) Up (b) up
4. (a) Up (b) down

9-25. What is the main purpose of a masking device in a contact printer?

1. It protects the glass from scratches
2. It allows the prints to be produced with white borders
3. It holds the paper in place
4. It separates the negative from the glass

9-26. When viewed under a light source, the emulsion side of (a) film and (b) paper have what appearance?

1. (a) Shiny (b) shiny
2. (a) Shiny (b) dull
3. (a) Dull (b) dull
4. (a) Dull (b) shiny

9-27. What affect occurs when the material used to mask a contact print is too thick?

1. The print requires an excessive amount of exposure
2. The print image is reversed
3. The image is blurred along the edges
4. The paper does not get exposed

9-28. What term describes the guide on a contact printer that aides quick and proper paper alignment?

1. Mask
2. Goldenrod
3. Paper stop
4. Print border mark

Learning Objective: Identify steps used to process black-and-white paper and control the contrast of black-and-white prints.

9-29. When hand processing black-and-white prints, the image on the paper should appear in what length of time, in seconds?

1. 30
2. 15
3. 10
4. 5

9-30. You made a contact print with a number 3 contrast printing filter, but the print lacks adequate contrast. Which of the following filters should you use to make the reprint?

1. No. 1
2. No. 2
3. No. 1 1/2
4. No. 4

- 9-31. In hand processing, the term "pull" refers to what action?
1. Pulling the print through the entire process
 2. Removing the print from the developer prematurely
 3. Pouring chemical solutions
 4. Removing prints from the dryer
- 9-32. A negative with normal contrast was printed with a No. 4 printing filter. Which of the following statements best describes the appearance of the prints?
1. The number of tones, reproduced matches the original scene tones closely
 2. The print shows an abundance of middle tones with few shadow areas
 3. The print is very flat
 4. The print has high contrast
- 9-33. When developing prints in a tray, you should ensure they are agitated in what manner?
1. Frequently
 2. Intermittently
 3. Constantly
 4. Infrequently
- 9-34. Which of the following statements is most accurate regarding print quality?
1. Print quality depends upon correct exposure only
 2. Print quality depends upon correct development only
 3. Print quality depends upon correct exposure and development
 4. Print quality is governed by the working characteristics of the paper and developer
- 9-35. You are hand processing a single black-and-white print. The print should be treated in the stop bath for what number of seconds?
1. 20
 2. 15
 3. 10
 4. 5
- 9-36. What is the most probable result of a fixing bath that is diluted less than recommended?
1. The prints sink
 2. The prints float
 3. The prints blister
 4. The prints separate from the base
- 9-37. When hand processing photographic film and paper, it is common practice to work in what direction?
1. From right to left
 2. From left to right
 3. From top to bottom
 4. From bottom to top
- 9-38. You are hand processing 26 8x10-inch prints at one time in a tray. You should agitate the prints in what manner?
1. Move the bottom print to the top of the stack
 2. Move the top print to the bottom of the stack
 3. Turn all the prints at one time and fan them quickly
 4. Remove each print in succession from the developer, drain it for 5 seconds, then place the print at the bottom of the stack
- 9-39. You are processing several black-and-white prints at one time. You should treat the prints in the stop bath for what number of seconds?
1. 15
 2. 30
 3. 60
 4. 90

9-40. After you remove a series of black-and-white prints from the dryer, you notice several of the prints have white fingerprints on them. What is the most probable cause of these fingerprints?

1. Fingerprints on the negative
2. Hands with developer on them touched the paper emulsion before processing
3. Hands with fixer on them touched the paper emulsion before processing
4. Dryer temperature was set too high and pressure from fingers made an indentation in the softened emulsion

9-41. To economize on the quantity of developer, you should use only enough solution to barely cover the paper.

1. True
2. False

Learning Objective: Identify methods used in projection printing.

9-42. "Dodging" and "burning in" are terms that best describe what type of control?

1. Contrast
2. Process
3. Exposure
4. Sensitivity

9-43. What method of printing allows you to correct for distortion?

1. Contact
2. Projection

9-44. A 4x5-inch negative is enlarged so the entire negative image is reproduced on an 8x10-inch print. What is the image magnification of this print?

1. 1x
2. 2x
3. 3x
4. 4x

9-45. All other factors being equal, what type of enlarger produces the greatest print contrast?

1. Condenser
2. Diffusion
3. Condenser-diffusion

9-46. What type of enlarger should you use to obscure negative defects?

1. Condenser
2. Diffusion
3. Condenser-diffusion

9-47. What type of black-and-white enlarger is used most commonly for general printing in Navy imaging facilities?

1. Condenser
2. Diffusion
3. Condenser-diffusion

9-48. Any high-quality camera lens can be used on an enlarger to produce high-quality prints.

1. True
2. False

9-49. You are printing a 4x5-inch negative. Which of the following focal-length enlarger lenses should you use?

1. 50mm
2. 75mm
3. 105mm
4. 150mm

9-50. With a lens-to-paper distance of 24 inches and all other factors being equal, which of the following focal-length lenses provides the greatest image magnification?

1. 50mm
2. 75mm
3. 105mm
4. 150mm

9-51. When photographic enlargements are being made, the term "cropping" is used to describe what procedure?

1. Setting the timer
2. Setting the aperture
3. Composing the image
4. Processing the prints

9-52. You made a test print without a contrast printing filter using an exposure of 10 seconds at f/11. The test print looks flat and you are going to make another test print using a No. 4 Ilford Multigrade printing filter. Keeping the timer on 10 seconds, you should make the new test print at what f/stop?

1. f/16
2. f/11
3. f/8
4. f/5.6

9-53. Which of the following printing techniques should you use to subdue facial blemishes;?

1. Dodging
2. Burning in
3. Diffusing
4. Vignetting

9-54. A negative you are printing has objectional grain structure. Which of the following techniques should you use to minimize this affect to the greatest extent?

1. Use a diffusion enlarger and glossy paper
2. Use a diffusion enlarger with matte-surfaced paper
3. Use a condenser enlarger and glossy paper
4. Use a condenser enlarger with matte-surfaced paper

9-55. In which of the following circumstances might you be concerned with depth of field when making enlargements?

1. When using dodging techniques
2. When using variable contrast papers
3. When printing a 35mm negative of a tall building
4. When the negative image shows shallow depth of field

Learning Objective: Recognize basic principles used in color printing.

9-56. What is the resulting color when blue is removed from white light?

1. Yellow
2. Green
3. Red
4. Magenta

9-57. What are the colors of the additive primaries?

1. White, gray, and black
2. Cyan, magenta, and yellow
3. Red, green, and yellow
4. Red, green, and blue

9-58. What are the colors of the additive secondaries and the subtractive primaries?

1. Red, green, and blue
2. Cyan, magenta, and yellow
3. Red, green, and yellow
4. White, gray, and black

9-59. The middle emulsion layer of color paper is sensitive to what color(s)?

1. Yellow
2. Red
3. Green
4. Each of the above

COLOR	
1.	Green
2.	Blue
3.	Red
4.	Orange

Figure 9A

IN ANSWERING QUESTIONS 9-60 THROUGH 9-62, REFER TO FIGURE 9A AND SELECT THE COLOR THAT RESULTS BY MIXING THE COLORS USED AS THE QUESTION.

9-60. Magenta and yellow:

1. 1
2. 2
3. 3
4. 4

9-61. Cyan and yellow:

1. 1
2. 2
3. 3
4. 4

9-62. Magenta and cyan:

1. 1
2. 2
3. 3
4. 4

9-63. What filter is used to remove ultraviolet radiation emitted by the light source of a color enlarger?

1. CC red
2. CP yellow
3. IR7
4. CP2B

9-64. A color enlarger lamp is designed to operate on 115 volts but is only receiving 95 volts. The color change of the output of the lamp is equivalent to what No. CC filter?

1. 05
2. 10
3. 15
4. 20

9-65. During exposure, the color paper received an excessive amount of green light. The processed print has what color cast?

1. Green
2. Magenta
3. Cyan
4. Yellow

9-66. When you are evaluating a color test print, the viewing light source should produce (a) what Kelvin temperature at (b) what number of footcandles of illuminance, and (c) what should the CRI be?

1. (a) 3950 (b) 55 (c) 90
2. (a) 4000 (b) 195 (c) 130
3. (a) 5000 (b) 100 (c) 95
4. (a) 5400 (b) 130 (c) 100

9-67. You are using color printing viewing filters to determine the color balance of a test print. On what areas of the print should you base your judgment?

1. Highlights
2. Shadows
3. Borders
4. Middle tones

9-68. The gray area in a color print has a red cast to it. Therefore, the light used to expose the print was deficient in what color?

1. Yellow
2. Red
3. Cyan
4. Blue

- 9-69. A color test print has a yellow color cast. Using a subtractive type of printer, you should make what modification to the filter pack?
1. Subtract yellow only
 2. Add yellow only
 3. Add blue only
 4. Add magenta and cyan
- 9-70. Your calculated color printing filter pack is CC10Y + CC15M + CC05C. What should the actual filter pack be for the reprint?
1. CC15Y + CC25M only
 2. CC15Y + CC25M + CC10C
 3. CC05Y + CC15M only
 4. CC05Y + CC15M + CC05C
- 9-71. A color test print has a blue color cast. Using an additive type of printer, you should make which of the following adjustments?
1. Add blue
 2. Subtract blue
 3. Add yellow
 4. Either 2 or 3 above
- 9-72. What is the purpose of a standard negative?
1. It is used as a comparison of negative printing qualities
 2. It serves as a tool to compare the printing characteristics of different emulsions
 3. It can be used to program color analyzers and automated printers
 4. Each of the above
- 9-73. You took portraits of four sailors. Each sailor had distinctly different skin tones; however, after the negatives were printed, all the skin tones were depicted alike. What is the most probable cause of error?
1. A skin tone was used for negative evaluation
 2. The studio lights were the wrong Kelvin temperature
 3. The same portrait lights were used to photograph all four sailors
 4. The characteristics of the negative-positive system are such that all skin tones are reproduced alike
- 9-74. You are processing color prints using the RA-4 process. What is the approximate total processing time in minutes?
1. 2 3/4
 2. 4 1/2
 3. 8 1/4
 4. 12
- 9-75. Which of the following characteristics apply to a minilab system?
1. It requires maintenance
 2. It is capable of producing a high volume of prints
 3. It is operated under normal lighting conditions
 4. Each of the above

ASSIGNMENT 10

Textbook Assignment: "Motion Media," and "Job Control and Photographic Finishing." Pages 13-1 through 14-13.

Learning Objective: Identify basic principles of motion-picture photography.

- 10-1. What is the normal frames-per-second rate for motion pictures?
1. 12
 2. 24
 3. 48
 4. 96
- 10-2. What characteristic of human vision contributes to the illusion of motion in motion-picture photography?
1. Persistence of vision
 2. Image perception
 3. Chromatic stimulation
 4. Visual frequency response
- 10-3. With normal persistence of vision, the "after image" lasts approximately what length of time?
1. $\frac{1}{2}$
 2. $\frac{1}{4}$
 3. $\frac{1}{10}$
 4. $\frac{1}{50}$
- 10-4. Each picture area on a strip of motion-picture film is referred to by what term?
1. Cut
 2. Shot
 3. Frame
 4. Clip
- 10-5. What is the standard projection speed for a motion-picture film?
1. 8 fps
 2. 16 fps
 3. 24 fps
 4. 36 fps
- 10-6. A motion-picture film shot at which of the following fps rates produces the illusion of slow motion?
1. 6 fps
 2. 12 fps
 3. 24 fps
 4. 48 fps
- 10-7. What is the normal focal-length lens for a 16mm camera?
1. 50mm
 2. 35mm
 3. 25mm
 4. 16mm
- 10-8. What is the result when a motion-picture camera is panned with a polarizing filter over the lens?
1. Variable darkening of the sky as the camera is panned
 2. The polarizing grids cause the image to flicker
 3. Excessive sky contrast results from the inability of the filter to rotate at the same rate as the camera is panned
 4. Interference lines caused by the polarizing grids and the frame lines being out of synchronization
- 10-9. Which of the following is NOT an exposure controlling factor in motion-picture photography?
1. Film speed
 2. Shutter speed
 3. f/stop
 4. Lens filter

10-10. A motion-picture camera operating at the standard speed with a shutter degree opening of 168 degrees has what approximate shutter speed?

1. 1/500 second
2. 1/250 second
3. 1/100 second
4. 1/50 second

Learning Objective: Recognize basic principles of motion video.

10-11. Motion video has which of the following advantages over motion-picture photography?

1. Film processing is not required
2. It is edited more quickly
3. Videotape is easily duplicated
4. Each of the above

10-12. In a color video camera, what device separates white light into the three primary colors?

1. The color separator
2. The beam splitter
3. The automatic gain control
4. The frequency generator

10-13. What is the aspect ratio of a motion-video frame?

1. 2:1
2. 2:3
3. 3:4
4. 3:5

10-14. What term describes unwanted sounds or electrical interference in an audio or video signal?

1. Dropout
2. Capstan
3. Dub
4. Noise

10-15. What term depicts the smallest single picture element from which an image is constructed?

1. Frame
2. Field
3. Pixel
4. Composite

10-16. In a composite video signal, what does "Y" represent?

1. Yellow
2. Luminance
3. Color
4. Sound

10-17. What is/are the main cause(s) of dropout?

1. Poor microphone connection
2. Dirty heads
3. Imperfections in the tape
4. Both 2 and 3 above

10-18. What component in a video camera serves the same purpose as film in a motion-picture camera?

1. The cathode-ray tube
2. The charged-coupled imaging device
3. The beam splitter
4. The character generator

10-19. One complete television image is composed of what number of fields?

1. One
2. Two
3. Three
4. Four

10-20. A complete charge-forming-and-scanning process within a motion-video camera occurs what number of times per second?

1. 10
2. 20
3. 30
4. 60

10-21. Information from what section of a videotape allows the tape to be played on different but similar types of video players?

1. Control track
2. Video monitor
3. Video synchronizer
4. Helical control

10-22. The Hi8 system is completely compatible with all other recording systems.

1. True
2. False

Learning Objective: Identify guidelines used when shooting motion-picture photography.

10-23. You recorded a scene on a camcorder and the image appears grainy and flat. This appearance probably occurred due to which of the following causes?

1. A high-speed videotape was used
2. The scene brightness level was too high
3. The scene brightness level was too low
4. The gain was accidentally increased during recording

10-24. In which of the following situations should you manually focus a camcorder while recording a scene?

1. When the subject is extremely backlit
2. When the scene contains little contrast
3. When moving objects pass between the camera and the subject
4. Each of the above

10-25. Which of the following focal-length lenses should you use while shooting a motion-media scene from a moving boat?

1. 15mm
2. 25mm
3. 50mm
4. 75mm

10-26. What is the first rule of panning with a motion-media camera?

1. Pan from left to right
2. Pan only when using a fast shutter speed
3. Pan only when necessary
4. Pan with a short focal-length lens

10-27. Primary movement refers to the visual effect of motion that is created by what source?

1. Single camera
2. Multiple cameras
3. Computer graphics
4. The subject

10-28. What motion-media shot is used to tell where the action takes place?

1. ELS
2. LS
3. MS
4. CU

10-29. What motion-media shot is used to tell what action is taking place?

1. ELS
2. LS
3. MS
4. CU

10-30. What motion-media shot is used to present only action of primary interest?

1. ELS
2. LS
3. MS
4. CU

- 10-31. You made several shots of a subject using different camera angles. However, in one shot the background appears much different and looks as though it was shot in a different location. What rule of videography did you violate?
1. Action match
 2. Shot variety
 3. Continuity
 4. Sequential shooting
- 10-32. The subject of a video is shown moving directly toward the viewer. What type of screen direction is portrayed?
1. Forward
 2. Neutral
 3. Head on
 4. Nondirectional
- 10-33. What type of shot is made when the video camera is moved to follow a subject creating neutral screen direction?
1. Traveling abreast
 2. Constant screen direction
 3. Tracking
 4. Direction of travel
- 10-34. You are videotaping a baseball game. During the game, you shot several scenes of a boy eating a hot dog. This is what type of shot?
1. Reestablishing
 2. Establishing
 3. Cutaway
 4. Cut in
- 10-35. You are videotaping a soccer game. During the game, one of the players kicks the ball into the face of the referee. During halftime, you shoot a reenactment of the event. This is what type of shot?
1. Reestablishing
 2. Establishing
 3. Cutaway
 4. Cut in
- 10-36. As a Navy Photographer's Mate, you can expect most of your motion-media work to be of the uncontrolled-action type.
1. True
 2. False
- 10-37. What is the purpose of slating videotape?
1. To identify the film
 2. To ensure the camera is operating at the proper speed
 3. To take up slack in the cassette
 4. To color balance the camera on a neutral-gray colored object
- 10-38. A slate should be recorded for what minimum number of seconds?
1. 30
 2. 20
 3. 3
 4. 10
- 10-39. What form must accompany all media products forwarded to a Still and Motion-Media Records Center?
1. Video/film data sheet
 2. Visual information caption sheet
 3. Photographic job order
 4. NAVAIR form 12700
- 10-40. Videotapes should be stored in what manner?
1. Upright only
 2. Horizontally but not more than five high
 3. Horizontally but not more than ten high
 4. It makes no difference since videotapes are extremely durable

Learning Objective: Recognize security procedures used in Navy imaging facilities.

- 10-41. Security-related information pertaining to the Navy is contained in what instruction?
1. OPNAVINST 5290.1
 2. OPNAVINST 5510.1
 3. SECNAVINST 3150.6
 4. SECNAVINST 5212.5
- 10-42. Only those Photographer's Mates with a security clearance are responsible for safeguarding classified material.
1. True
 2. False
- 10-43. Security classifications are categorized in what number of designations?
1. One
 2. Two
 3. Three
 4. Four
- 10-44. What is the highest security classification?
1. Cryptographic
 2. Cosmic
 3. Exclusion
 4. Top Secret
- 10-45. At a Las Vegas hotel, you shot several rolls of film about sailors conducting themselves in actions that are unbecoming. These photographs could be detrimental to their careers and cause them much embarrassment. What classification, if any, should these photographs bear?
1. Secret
 2. Confidential
 3. For Official Use Only
 4. None

- 10-46. A roll of film that contains images of classified information should be marked in what manner?
1. On the emulsion side beneath each frame
 2. On the emulsion side at the beginning and end of the roll
 3. On the base side beneath each frame
 4. On the base side at the beginning and end of the roll
- 10-47. Classified 8x10-inch prints should be marked with the appropriate classification in what number of places?
1. One
 2. Two
 3. Three
 4. Four
- 10-48. A classified videotape should be marked appropriately in what location(s)?
1. At the beginning of the videotape only
 2. At the end of the videotape only
 3. On the tape case only
 4. At the beginning and end of the videotape as well as on the tape case
- 10-49. As a Photographer's Mate, you must protect classified material by what means?
1. Censorship and transmission
 2. Cryptographic and transmission
 3. Censorship and physical
 4. Physical and cryptographic
- 10-50. A record of destruction of Top Secret material must be retained for what number of years?
1. 1
 2. 2
 3. 3
 4. 4

- 10-51. What type of security area requires the strictest access control?
1. Restricted
 2. Controlled
 3. Limited
 4. Exclusion
- 10-52. What person is directly responsible for safeguarding classified material in an imaging facility?
1. The division officer
 2. The department head
 3. The commanding officer
 4. The security manager
- 10-53. Which of the following items should NOT be stored in a class A vault?
1. Top Secret
 2. Secret
 3. Confidential
 4. Imprest funds
- 10-54. The combination to a safe used to store classified material must be changed at an interval not to exceed what period of time?
1. 1 year
 2. 6 months
 3. 3 months
 4. 1 month
- 10-55. Which of the following combinations should NOT be used for a safe containing classified material?
1. 6-37-50
 2. 5-10-15
 3. 22-47-9
 4. 2-53-12
- 10-56. When a safe is taken out of service, it should be reset to what combination?
1. 50-25-50
 2. 25-50-25
 3. 10-20-30
 4. 5-10-15
-
- Learning Objective: Recognize administrative procedures used in Navy imaging facilities.
-
- 10-57. Navy imaging administrative and operating procedures are contained in what instruction?
1. OPNAVINST 5290.1
 2. NAVEDTRA 13014
 3. SECNAVINST 3150.6
 4. NAVAIRSYSCOMINST 10700.2
- 10-58. The job order number in the job order log should be reset annually to 000001 on what date?
1. 1 January
 2. 1 April
 3. 1 August
 4. 1 October
- 10-59. The job order form serves what purpose?
1. As a customer receipt
 2. As an authority to perform work
 3. As a record of expenditures
 4. Each of the above
- 10-60. A color negative is identified by what VIRIN code?
1. SCN
 2. VPS
 3. CLN
 4. CLR
- 10-61. You are preparing the VIRIN for an unclassified, color slide that was shot on 10OCT93. Which of the following examples is appropriate for the slide?
1. N0341-SPT-93-000020
 2. N0341-SPT-94-000020
 3. N0341-SPT-93-000020-UC
 4. N0341-SCS-94-000020

10-62. The VIRIN of a videotape cassette should be recorded at the beginning of the tape for a minimum of what viewing time, in seconds?

1. 5
2. 10
3. 15
4. 30

10-63. All Navy imaging products forwarded to a Visual Information Records Center for preaccessioning must be accompanied by what form?

1. DD Form 10700
2. DD Form 2537
3. DD Form 1348
4. OPNAV 5290/1

Learning Objective: Identify methods used to mount prints.

10-64. Normally, prints are mounted in which of the following ways?

1. With all borders equal
2. With the top border being the widest
3. With the bottom border being the widest
4. With a mounting board that has loud, contrasting color

10-65. Which of the following adhesives should you use to mount photographic prints on a mounting board?

1. Rubber cement
2. Gum arabic
3. Paste
4. Glue

COLOR printer.

PREFACE

About this course:

This is a self-study course. By studying this course, you can improve your professional/military knowledge, as well as prepare for the Navywide advancement-in-rate examination. It contains subject matter about day-to-day occupational knowledge and skill requirements and includes text, tables, and illustrations to help you understand the information. An additional important feature of this course is its references to useful information to be found in other publications. The well-prepared Sailor will take the time to look up the additional information.

Any errata for this course can be found at <https://www.advancement.cnet.navy.mil> under Products.

History of the course:

- Apr 2002: Original edition released.
- Apr 2003: Administrative update released. Technical content was not reviewed or revised.

ASSIGNMENT QUESTIONS follow Index.

CHAPTER 1

THE NAVY JOURNALIST

To the young man or woman choosing a Navy career field, whether for one enlistment or for 30 years, the journalist rating offers endless avenues for an imaginative, yet mature, thinker.

Many of the duties and responsibilities of the journalist rank among Americans' favorite hobbies and pastimes, such as writing, broadcasting and photography. The Navy Journalist learns and practices a distinguished profession and becomes an official representative of the Navy in public affairs matters (fig 1-1).

The first enlisted specialists to work full-time in the field of Navy Journalism were Naval Reserve personnel selected during the early years of World War II. They were designated Specialist X (Naval Correspondents). In 1948, under a major overhaul affecting almost every enlisted rating, the Journalist (JO) rating was established.

MAJOR TASKS AND RESPONSIBILITIES

LEARNING OBJECTIVE: Identify the major tasks and responsibilities of the Navy Journalist, the personal traits required for one to best perform the duties of the rating, the applicable NECs, and the purpose of the JO Basic Nonresident Training Course (NRTC).

Figure 1-1.—A Navy Journalist is a representative of the Navy in public affairs matters.

In our democratic society, government depends on the consent of the governed. This important principle means that, in the long run, the United States government does only what the people want it to do. Therefore, we can have a Navy only if the people know and understand the importance of the Navy and support it.

The Navy, like the other services, depends on this country's citizens for the four key tools of its trade—personnel, money, materials and the authority to carry out its mission. As a Navy Journalist, your main function will be to make the facts about your Navy available to the Navy's three main publics—the people at your ship or station, Navy people in general and the people of the United States as a whole.

Your CO is responsible for informing the Navy's publics. Your responsibility is to assist your command's public affairs officer (PAO) in accomplishing the Navy's and the command's public affairs goals.

Some of the key assignments for Navy Journalists include the following:

- Writing Navy news releases and feature articles from personal interviews, examination of messages or witnessing events
- Taking and processing news photographs and writing cutlines
- Preparing material for commercial radio and television use
- Serving on the staff of an American Forces Radio and Television (AFRTS) station or Naval Media Center (NMC) Broadcasting detachment as an interviewer or announcer (subject to the requirements for voice quality, public speaking, presence and sense of timing)
- Preparing command histories and CO, XO and C/MC biographies
- Rewriting and localizing news releases received from the Navy Internal Relations Activity (NIRA) and other sources throughout the naval establishment
- Coordinating special events

- Editing material and preparing copy, art and layouts for the printing of Navy publications, such as ship and station newspapers, command information brochures, welcome aboard brochures, cruisebooks and fact sheets
- Assisting in the preparation of speeches and other presentations on naval topics
- Preparing material on individual Navy members for release to the Navy's Fleet Home Town News Center
- Preparing official correspondence and directives and performing other administrative functions in a public affairs office
- Design, update and implement command World Wide Web sites and Internet homepages

To perform these duties well, you need to master verbal, oral and visual communication techniques. You must be a constant reader who is always abreast of current events in and out of the Navy. You must know enough about the Navy to interpret and translate its activities and actions intelligently to the civilian public. In the performance of their duties, journalists are expected to produce smooth copies of their own material. Therefore, you must be a qualified typist who meets the established standards for speed and accuracy. You also must be computer literate.

Finally, you as a journalist must have the ability to learn, and your main learning objective must be learning to write well. You must be better than average in your use of the English language. You must learn to write quickly, plainly and accurately. Your aim is to turn out news copy that can be used by a newspaper or radio/television station with a minimal need for editing or rewriting.

The major areas in which you will be expected to develop knowledge and skills include newswriting, editing and the layout and makeup of Navy publications. Other areas are the principles of printing, radio and television, still and digital photography and administration.

As you progress in experience, maturity and service seniority, you likely will become the trusted executive of the PAO. As such, you will find yourself performing many of the functions of a PAO. This will be particularly true if your boss is a collateral-duty PAO. Collateral duty means that the officer has other assignments that are considered primary duties. In such cases his primary responsibilities often allow only minimum time for public affairs work. Therefore,

you also must learn the theory and practice of public affairs policy.

A COMMON MISPERCEPTION

There is a tendency for Navy Journalists to believe they are part of America's free press and thus part of the investigative journalist corps. This notion could not be further from the truth.

The moniker "Navy Journalist" is misleading because the JO is a **public information specialist**—not a free press journalist. Navy Journalists are assigned to command information, public information and community relations duties. When assigned to public information staffs, Navy Journalists write releases to tell the Navy story and to respond to queries by the investigative free press. When assigned to command information staffs, Navy Journalists may write for civilian enterprise (CE) or funded command newspapers—what the industry terms "in-house" publications.

Just as a writer for commercial industry would not write investigative articles concerning his company for the in-house publication, Navy Journalists would not write investigatively concerning their own individual commands or the Navy. Navy Journalists may tackle controversial social issues in print or on videotape, but they must avoid works that attack or injure, or that give the impression of attacking or injuring their commands or the Navy.

NEWS IN THE NAVY COMMUNITY

New Navy Journalists are often confused about their role in the Navy community. Most are familiar with the print and electronic media back home. They are used to the civilian reporter investigating, or reporting on the investigation of fraud, waste or abuse in the local, county or state government.

In arriving at their first duty assignment, they find a community that seems to be somewhat similar to that of their hometown. The CO seems to be the mayor, and the chief master-at-arms represents the chief of police. The CO's staff fills the rest of the government positions. There are schools, stores, businesses and recreational services.

However, Navy Journalists must learn that the CO is not so much a mayor as he is the president of a company. Likewise, the Navy community is really much like a company town. Your job within this community is to enhance morale, to increase readiness

and productivity, to be the voice of the CO to his community, and to inform, educate and entertain the Navy's internal audience.

PERSONAL TRAITS

To accomplish the assignments previously mentioned, the Navy Journalist must have certain personal characteristics. Some are general characteristics that contribute to success in any rating, but others are an integral part of the public affairs profession. The characteristics of appearance, voice, military bearing, courtesy and personality will become more evident as you read and complete this Nonresident Training Course (NRTC).

APPEARANCE

Good personal appearance is especially important to the Navy Journalist. Most of your work will be relatively clean in nature, so it is possible to work hard and still look neat. Since your duties place you in a position to meet visitors, escort reporters, interview VIPs, act as a tour guide, and so forth, good appearance is more necessary than in some other jobs in the Navy. Always make sure every aspect of your personal appearance, from your haircut to the edge dressing on your shoes, is first-rate.

VOICE

Voice and manner of speaking are important. You should avoid an overly loud voice; but likewise, you should avoid speaking too low or indistinctly. Localisms of vocabulary or accent may be merely pleasant marks of individuality, or they may be hindrances because they make the speaker hard to understand. If you have conspicuous speech habits of this sort, you should attempt to correct them. Your attention to pronunciation of words will always be worthwhile.

MILITARY BEARING

All petty officers have an obligation to conduct themselves with dignity and in such a manner as to reflect credit on the naval service. Dignity exists only where the individual has a proper sense of his own worth and of the worthiness of his cause. The person who possesses true dignity also will respect the dignity of others.

Military bearing is dignity within military relationships. It exists when the individual is proud of his military organization and of his part in it. He respects his seniors and is guided by the example of those he admires most among them. He also respects his juniors and tries to provide an example they will be proud to follow. Whether he is squaring his hat, rendering a salute, carrying on the work of his office, or going on liberty, his manner says that he is proud of the Navy and is doing his best to make the Navy proud of him.

COURTESY

The qualifications for advancement do not list courtesy as a requirement, but they imply it. Most situations require a certain minimum standard in terms of manners, and unless we display this standard, we are in trouble. Courtesy goes far beyond that. It is in fact totally different in character, because courtesy comes from within and is a voluntary expression of respect for the rights and feelings of others. How your job as a journalist involves your interaction with others is emphasized throughout this NRTC. More than any other rating in the Navy, you will be associated primarily with people in the civilian populace. Courtesy on your part will smooth the way not only for you, but also for your command, your seniors and the people who work for you.

PERSONALITY

A pleasing personality is a must in the journalist rating. You must be able to get along with your shipmates, because their cooperation is necessary before you can carry out your duties. Always strive to establish a good name for the JO community. When you have the confidence of your shipmates, your job will be 100 percent easier.

NAVY ENLISTED CLASSIFICATIONS

Navy Enlisted Classifications (NECs) are four-digit numbers that indicate special qualifications earned by an individual. Currently, there are three NECs available to Navy Journalists, as described in the following text.

JO-3251—BROADCAST OPERATIONS DIRECTOR

Individuals with this NEC direct the operations of radio, television, satellite, cable and SITE support

systems as coordinated elements of the command information broadcasting function. Other key tasks include conducting research and planning programming, production, budgeting, training and maintenance.

This NEC could be part of your long-range career planning. You earn this NEC by graduating from the Broadcast Managers Course (BMC) at the Defense Information School (DINFOS); see fig 1-2.

PH-8147—PHOTOJOURNALISM SPECIALIST

Although this is primarily a Photographer's Mate NEC, members of the JO rating also may earn it. Sailors with this NEC cover and photograph events of news or documentary interest, while supporting and effectively meeting the public affairs objectives and programs of the military services. They apply layout and design principles, news and feature writing, basic and advanced photographic techniques and production, and demonstrate writing and photographic skills.

To earn this NEC, you must first complete the eight-week Intermediate Photojournalism Course (IPC) offered at the DINFOS (JO "B" School), then perform as a photojournalist in the field for one year. Your CO must forward an endorsement to the DINFOS before the NEC is approved and awarded.

PH-8148—PHOTOJOURNALIST

Sailors with the PH-8148 NEC photograph newsworthy events, prepare photography in news form, write captions and text for news stories, and maintain liaison with their counterparts in the news media. They also train personnel in photojournalism techniques.

You can earn this NEC by applying for acceptance to PH/JO "C" School at the Syracuse University. This fully accredited curriculum includes a minimum of 18 semester hours (30 quarter hours) of advanced

Figure 1-2.—An individual with a JO-3251 NEC can direct the operations of radio, television, satellite, cable and SITE support system.

photojournalism techniques and practices, including picture editing, newswriting and reporting, feature article writing, graphic arts, layouts, design, ethics in journalism, and many others. The NEC is awarded after your successful completion of the course.

You may obtain further information on all 3 NECs by consulting the *Manual of Navy Enlisted Manpower and Personnel Classifications and Occupational Standards, Volume I (Navy Enlisted Classifications)*, NAVPERS 18068F.

NRTC PURPOSE

The purpose of this NRTC is to ensure the quality and integrity of Navy Journalist training. It is based on the most current (at the time of this writing) journalist occupational standards (OCCSTDS). Since OCCSTDS change periodically, be sure you check with your Educational Services Officer (ESO) for the most up-to-date OCCSTDS.

This NRTC will not make you an accomplished writer or a public affairs specialist overnight, but it can help. It contains many useful rules and tips that, if you learn and practice, will lead you down the path of success in one of the most exciting and rewarding ratings in the U.S. Navy.

CHAPTER 2

BASIC NEWSWRITING

What elements make a news story and how are they used to construct a story?

If you were to pose these questions to a group of reporters, it is probable that no two of them would give the same responses. However, all would most likely include in their answers a similar list of elements they consider necessary for a story to be newsworthy.

This chapter will include a list of elements and other essentials that will help you be successful in writing a basic news story (fig 2-1).

BASIC ELEMENTS OF A NEWS STORY

LEARNING OBJECTIVE: *Identify the basic elements of a news story.*

For the purposes of this NRTC, we will use the following 10 categories as those covering the major elements of news:

- Immediacy
- Proximity
- Consequence
- Conflict
- Oddity
- Sex

Figure 2-1.—Journalists apply skills they learn at the Defense Information School in the fleet.
(Photo by JOC Pricilla Krish)

- Emotion
- Prominence
- Suspense
- Progress

If any one of these elements is present, a story has news value. However, many stories contain more than one element. Remember this latter fact as you study the material that follows because even though the 10 elements are used as the framework of this discussion, several of the examples given might just as well be discussed under different elements.

Remember, too, this is just one possible classification; another textbook might have classified these elements in slightly different categories. Rather than memorizing a set of categories, your chief concern should be to develop your understanding of what constitutes an interesting news story.

IMMEDIACY

A story that has just happened is news; one that happened a few days ago is history. Immediacy is timeliness. Few events of major significance can stand up as news if they fail to meet the test of timeliness. There is no point in submitting a news release on a routine change of command that occurred 4 days ago; the event is not big enough to overcome the time lag. A newspaper looks foolish if it publishes a news story, and after reading it, a subscriber says, “I heard about that 2 days ago.”

However, an event that occurred some time ago may still be timely if it has just been revealed. Examples are a newly discovered diary of John Paul Jones or the disclosure of a startling scientific accomplishment that occurred months ago, but has just been declassified. In these cases, the immediacy element revolves around the fact that the news was revealed or disclosed **today**. An up-to-the-minute touch is provided by words such as “newly disclosed,” “revealed,” “divulged” or “announced today.”

PROXIMITY

Readers are interested in what happens close to them. Proximity is the nearness of an event to the readers or listeners and how closely it touches their lives. People are interested mainly in themselves, their families, their ships or stations, their friends, and their hometowns. If Captian Gunn relieves Captian Stone as commanding officer of Naval Station Annapolis, it is news in the Annapolis, Baltimore and Washington areas and in the two officers' hometowns. It is not news in Huntsville, Ala., where no one knows either captain or cares particularly who commands a naval station in Maryland. Improvement or progress stories are important in their degree of proximity.

The Navy's hometown news program is based on this element. When Thomas Katt, Seaman Apprentice, USN, reports to USS *Pine*, it is news for his hometown paper. Back home in Hialeah, Fla., he is not Navy Seaman Apprentice Thomas Katt. He is Mr. Michael Katt's son, Thomas, who used to help his father rebuild homes devastated by Hurricane Andrew. He is someone the readers know. The element of proximity is present to a high degree. Further information on hometown news is in chapter 17.

CONSEQUENCE

News of change or news that affects human relations is news of consequence. The more people affected, the greater the news value. A story on the advancement of 1,500 petty officers has consequence within the Navy, especially to those who took the exams. A congressional act that raises the pay of everyone in the armed forces is of great consequence both to the Navy and to the public.

CONFLICT

Sporting events, wars and revolutions are the most common examples of conflict in the news. Man may be pitted against man, team against team, nation against nation or man against the natural elements. A story about a pilot struggling to land a crippled plane or a coxswain's heroic efforts to keep his crowded boat from swamping in heavy seas are other examples.

ODDITY

The unusual or strange event will help lift a story out of the ordinary. If an ordinary pilot parachuted out of an ordinary plane with an ordinary parachute and makes an ordinary landing, there is no real news value.

However, if the aviator has only one leg, this is news; or if the parachute fails to open and the pilot lands safely, this is news. A Sailor named B. A. Sailor is a good angle. So is the helicopter that towed a ship, the man that bit his dog or the plane that landed even though the pilot had bailed out.

SEX

Sometimes sex is the biggest single element in news, or at least it appears to be the element that attracts readers the most. Consider all the stories in papers that involve men and women—sports, financial news, society and crime. Sex, in discussing news elements, covers far more than a Hollywood star's impending visit to your command. The element of sex ranges from front-page sensationalism to news involving engagements and marriages.

Stories and accompanying pictures of movie stars or other prominent celebrities visiting your ship or station can be loaded with sex. Nevertheless, any type of news that overemphasizes the sexual element is in poor taste for an official Navy release and must be avoided.

EMOTION

The emotional element, sometimes called the human-interest element, covers all the feelings that human beings have, including happiness, sadness, anger, sympathy, ambition, hate, love, envy, generosity and humor. Emotion is comedy; emotion is tragedy; it is the interest man has in mankind. A good human-interest story can range from a real "tear jerker" to a rollicking farce.

PROMINENCE

Prominence is a one-word way of saying "names make news." When a person is prominent, like the President of the United States, almost anything he does is newsworthy—even his church attendance. Several hundred civilians may visit your ship or station in the course of a month without raising a stir. Yet, if one happens to be the governor of the state, you have a news story packed with prominence. Prominence is not restricted or reserved for VIPs only. Some places, things and events have prominence. For example, the White House (a place), the Hope Diamond (a thing) and Christmas (an event) all awaken interest.

SUSPENSE

You most often see the suspense element presented in a day-by-day or hour-by-hour account of some high-visibility event. Examples are a desperate search for a lost submarine, or a story of rescue operations in a mine where workers are trapped, or in the efforts made to rescue a Navy diver trapped in the wreckage of a sunken ship. A news story does not build to a climax as a mystery does. But, still cite the most important facts first. This practice helps to heighten the suspense of many stories because the ultimate outcome is unknown and is usually revealed through progressive, periodic installments.

PROGRESS

In our technologically advanced society, we are interested in space exploration. Therefore, developments of more powerful and advanced rockets to propel manned space flights are of great interest to most Americans.

Progress does not have to be dramatic. For example, an improvement in mooring lines, shoe leather or paper clips can be significant progress. There is a great deal of progress in Navy news stories. The Navy is constantly making progress in seamanship, weapons systems, aeronautics, nuclear propulsion, medicine, habitability, education, human relations, leadership and other fields.

IDENTIFICATION OF DOMINANT NEWS ELEMENTS

LEARNING OBJECTIVE: *Distinguish the dominant news elements in basic news stories.*

Just how are these key elements applied in judging the newsworthiness of an event?

First of all, the newsworthiness of a story depends on the strength or intensity of the news elements it contains—the more intense the elements, the more newsworthy the story.

After gathering material for a news story, you normally find that one or more elements overshadow the others in intensity. These are the **dominant elements**. This is sometimes referred to as the **news peg**.

NEWS PEG

A news peg is the most significant or interesting fact in a story. It is featured in the first paragraph, and all other facts revolve around it. In other words, it is a foundation around which you construct the facts of your story.

For just a few moments, put yourself in this hypothetical situation and assume that you are a JO assigned to the Public Affairs Office, NAS Moffett Field, Calif. The facts of the story, for which you have been given the task of readying for a 1400 release to the local media, are as follows:

1. Navy Lt John R. Doe, son of Mr. and Mrs. John Q. Doe of 1234 C St., Long Boat Calif., is a pilot attached to Fighter Squadron 44 at NAS Miramar.
2. At 9 a.m. (always use civilian terminology for civilian media), Lt Doe took off from the naval air station in a supersonic F-14 "Tomcat" for gunnery practice over the Mojave Desert.
3. At 9:20 a.m., while flying at an altitude of 13,000 feet, Lt Doe put his plane into a shallow dive and fired a few bursts from his cannon. When he pulled out of the dive a few seconds later, hydraulic warning lights lighted up like a Christmas tree.
4. Lt Doe fought desperately to control his damaged plane, but had to bail out.
5. Amazingly, the Tomcat landed in the desert. The plane's wings sheared off causing considerable damage, but the pilot escaped serious injury. He walked away from the crash, but collapsed from shock and loss of blood.
6. After an emergency blood transfusion and treatment for shock, Lt Doe is recovering at the NAS hospital. Doctors report that his condition is good.
7. A preliminary investigation into the cause of the accident revealed that Lt Doe's jet had lost hydraulic pressure.

Now that we know the facts in the story, let us see if we can determine the most dominant elements. Table 2-1 will help you analyze them. Elements have been classified in degrees of **very strong**, **strong**, **weak**, **very weak** and **none**.

As you can see, the elements of immediacy, proximity and oddity are listed as strong. They are dominant elements in this story, with oddity taking a decided edge over the other two. They will be combined in the news peg, which will be featured in the

Table 2-1.—Analyzing News Elements

News Element	Degree of Intensity	Justification
Immediacy	Strong	Accident occurred this morning. Story will be released this afternoon.
Proximity	Strong	Accident occurred locally. Squadron and pilot are attached locally.
Consequence	Weak	Measures will undoubtedly be taken to prevent further recurrence of this type, but this one incident in itself does not affect a great number of people.
Conflict	Weak	The pilot's struggle for survival is worth mentioning, but more details are necessary to make this element strong.
Oddity	Very Strong	Nothing like this has been recorded before.
Sex	None	-----
Emotion	Very Weak	The reader will sympathize with the pilot, but not beyond the extent one human being sympathizes for another human being in an unfortunate situation.
Prominence	None	The pilot is not widely known.
Suspense	Weak	Although the facts, as presented here, do not lend themselves to suspended interest, the story has a certain amount of drama and suspense.
Progress	Weak	Progress in aviation may eventually result from this situation, but there is nothing in the facts that will improve mankind's health, comfort or happiness.

beginning of the story. The news peg for this story could be written as follows:

"A Navy plane was shot down by its own gunfire near San Jose today. The plane, piloted by Lt. John R. Doe,...."

As the story is developed, the other facts are introduced to complement or supplement the dominant elements featured in the news peg.

Table 2-2 lists a few other examples of analyzing dominant elements for the news peg. The first element listed is the strongest. The others, if there are any, are supporting elements.

Note that immediacy and proximity are not listed as dominant elements, unless they actually overshadow the other elements. Immediacy is present in practically every story because the facts must be **new** to be considered **news**. Proximity also is present in practically every local story.

SPOT AND CREATED NEWS

Most Navy news (and all other news as well) can be classified as either **spot news** or **created news**.

Spot news just happens. A ship runs aground. A plane crashes. A heroic rescue takes place in a

Table 2-2.—Identifying Dominant News Elements

News Item	Dominant Element
Today is the final day for filing your annual income tax return.	Immediacy Consequence
A Navy flier, who braved enemy ground fire to locate a downed fellow airman over hostile territory, has been posthumously presented the Navy Cross.	Emotion
The Administration is near a final decision —perhaps it will come next week —on how much of a pay raise it will seek for the armed forces.	Consequence
The President of the United States submitted the names of 50 flag rank selectees to the senate for confirmation, including the name of Captian Mary Chairman. Captian Chairman, a Nurse Corps selectee, will be the Navy’s first woman flag officer.	Prominence/sex
Seaman A. B. Smith, son of Mr. and Mrs. A. C. Smith of Route 2, Fayetteville, Tenn., is currently patrolling the Western Pacific with the Seventh Fleet aboard the aircraft carrier USS <i>Kitty Hawk</i> .	Proximity (in the Fayetteville area)
A Navy officer, who had never taken control of an aircraft, brought an Air Force spotter plane in for a rough but successful landing recently. The incident came about after the pilot was killed by ground fire during a routine observation mission over enemy territory.	Oddity/Suspense
More new weapons systems than before, an improved retention rate, better housing and an increase in minority recruiting were some of the accomplishments that Paul T. Boate was proud to list from his 3 1/2 years as Secretary of the Navy.	Progress/Prominence
Navy sank Delaware, 24-3 today in the first ever Blue Crab Bowl at Navy-Marine Corps Memorial Stadium.	Conflict
The first female seaman qualified today as a deep-sea diver at the Navy Diving and Salvage School.	Sex/Oddity

storm-tossed sea. These are just a few examples. Your job is to provide a full account of a spot news story as soon as possible—even in cases where the general effect is unfavorable to the Navy.

Created news is generally concerned with something the Navy has done or plans to do that the public should know about. Examples include air shows, command public visitations, changes of command, unveiling new ships, planes or weapons, construction programs, special achievements, ship arrivals and many of the other daily events of Navy life.

Your job is to bring the information to the attention of news media, usually through a Navy news release.

CLASSES OF NEWS STORIES

Most Navy news stories fall into four main categories—hard news, feature, sports and social. They are described in the following text.

Hard News

The hard news story is designed primarily to inform. It usually concerns a news item involving or affecting the

readers, listeners or viewers. The hard news story has usually taken place since a previous issue of a newspaper radio or television newscast. Much of the material found in daily papers (especially front-page items) or newscasts are in the hard news category.

Feature News

The feature news story is about an event or situation that stirs the emotions or imagination. The event may or may not have taken place, or the situation may or may not have arisen since the last issue of a periodical or delivery of a newscast. The feature story is designed primarily to entertain, but it also serves to create interest or to inform the reader. It may be about a Sailor with the unusual hobby of collecting 18th-century etchings, a command that has adopted a stray goat as a mascot, a Navy cook who worked in a leading French restaurant before enlisting or, in a serious vein, the plight of a child who has been orphaned by an automobile accident.

Sports News

The sports news story may be handled as either hard news or a feature. These stories chronicle the activities of athletic teams, discuss upcoming games and detail the accomplishments of sports figures. In most cases of Navy sports, unless teams are prominent (such as that of the U.S. Naval Academy), the material is aimed at ship and station publications.

Social News

The social story, which may also be handled as either hard news or as a feature, primarily concerns wives, daughters and family activities. Most often Navy social stories deal with the activities of officers and enlisted wives' clubs, the happenings of the teen-age set, weddings and local charity events.

Other Categories

Other categories of stories frequently used in metropolitan newspapers include interpretive, science, consumer and financial.

INTERPRETIVE.—In an interpretive story, the reporter attempts to give an in-depth analysis and survey of the causes or possible consequences of important news events.

SCIENCE.—With this story, the reporter attempts to explain, in layman's language, scientific and technological news.

CONSUMER.—The writer of a consumer story attempts to help his audience buy more wisely, maintain products and homes better, cook or garden better and so forth.

FINANCIAL.—Writers of financial news focus on business, commercial or investment stories.

Writers of these stories are usually expected to have an academic background or experience in their subject matter, as well as the ability to observe and write well.

NEWS STYLE VS. LITERARY ENGLISH

LEARNING OBJECTIVE: *Recognize the differences between the news and literary English writing styles; identify the ABCs of journalism.*

Many great writers have been known for their dramatic styles, vivid descriptions, and the eloquent conversation of their characters. It is obvious, however, that these great writers were not concerned with news style writing or the fundamentals of newswriting. Consider the following quotation for example:

“It is a thing well known to both American and English whalers, and as well a thing placed upon authoritative record years ago by Scoresby, that some whales have been captured far north in the Pacific, in whose bodies have been found the barbs of harpoons darted in the Greenland seas. Nor is it to be gainsaid, that in some of these instances two assaults could not have exceeded very many days. Hence, the inference, it has been believed by some whalers, that the North West Passage, so long a problem to men, was never a problem to the whale.”

Perhaps this quotation is familiar to you. It is from *Moby Dick*, which is one of the greatest sea stories ever written. It was published more than 100 years ago and is still read today. Its author, Herman Melville, was known for his moving literary style.

A modern journalist writing this piece for a newspaper might put it on paper as follows:

“The Northwest Passage, long sought by man, may be known and used by whales.”

“American and British Sailors have reported finding the barbs of harpoons from Greenland in the bodies of whales killed in the

North Pacific. In some cases, the wounds were only a few days old. This has led some whalers to believe that whales must use some shortcut from the North Atlantic to the North Pacific.”

The preceding contrast shows the difference between literary writing of more than 100 years ago and newspaper English today.

Media writing is geared to the public, not the professor. The purpose is to inform, not to impress. All the frills are stripped away. Unnecessary wording costs the media money in terms of time (electronic) or space (print).

Newspapers are read in a hurry. They are read at breakfast, on the subway, against the blare of radio or television, or over someone’s shoulder. Many readers scan the headlines and read only the opening paragraphs of a few articles. These readers have neither the time nor the desire to wade through literary writing. Many may have limited educations. Surveys show that the average newspaper reader has the reading ability of a 12-year-old child.

Does this mean that you have to write for 12-year olds? No, it does not. We are not speaking of the readers’ ability to grasp ideas, but rather of their ability to understand difficult words. There is a great difference. For example, consider the following paragraph:

Gravitation is omnipresent; it is exerted by every body on every other body, no matter how remote or minute. Between two given objects, its force varies directly with the product of the two masses and inversely with the squares of the distance between their centers. Exerting itself throughout the universe, it is gravitation that keeps the cosmos in equilibrium.

This paragraph is obviously too difficult for an adult with a 12-year old reading level. Yet the adult mind could grasp the idea involved if we translate the paragraph into simple English such as follows:

All bodies attract each other. This is true no matter how small or far apart they may be. The heavier two objects are, the more they pull on each other. The farther apart they are, the weaker this force becomes. In measuring the pull, distance is particularly important, for if you double the distance, the force is cut to one-fourth of its former strength. This force is called gravitation. Because of it, the earth,

sun, moon and stars all pull against each other. The forces balance, and everything stays in its proper place.

Almost any idea, no matter how complicated, can be expressed in simple language. As a Navy Journalist, you may have to explain some fairly technical ideas to readers who are not familiar with military life. You will have to do it in language they will understand. It is up to you to do the work of simplification, **not your readers**. If they find your writing is “over their heads,” they will skip your piece and go on to something that is easier to read. If this happens, you are not doing your job.

Also remember —the story you write for the general news media will probably be read by someone with a Ph.D. How do you satisfy both? A good writer can present the information so that the less educated can understand and so that the more intelligent will not become bored.

THE ABC’S OF JOURNALISM

Some principles of newswriting you must apply every time you attempt to put words on paper include accuracy, brevity, clarity, coherence, emphasis, objectivity and unity.

ACCURACY

If a writer has to pick one principle that should never be violated, **accuracy** should be the one. To fall down in this area is to discredit your entire writing effort. As a JO, you will be working with facts. These facts will involve persons, places and things. The facts will involve names, ages, titles, rank or ratings, addresses and descriptions. You will work with facts that are both familiar and unfamiliar to you.

You cannot afford to be casual in your approach to facts. Your readers will often judge the Navy on what you say and how you say it. An easy way to lose the public’s respect and confidence is by being careless in your handling of facts. When you send a story to a newspaper, the editor depends on you for accuracy in every fact.

The Navy news release heading that appears on every story you distribute means the information it contains is reliable and has been approved officially by the Navy. A mistake in a news story implies that the Navy is careless and undependable. Datelines tell when and where the story is written and should appear on all stories written for release. In the text of the story, when and where may refer to the dateline.

Attribution relates to accuracy. It means that you name the person who makes any statement that may be challenged. Good quotations liven a story, give it color, and aid in development of coherence. Attribution also ensures that the reader does not get the impression the statement is the writer's personal opinion. However, attribution should never be used in a story merely to flatter a person by publicizing his or her name.

BREVITY

The question is often asked, "Should I be brief in my writing or complete?" By all means, be brief, but not at the expense of completeness. The key is to boil down your writing and eliminate garbage. A compact piece of writing is frequently much stronger than a lengthy story. An example is Lincoln's Gettysburg Address. This speech has outlived a flock of long harangues by later statesmen. One of the reasons for its survival is its brevity.

CLARITY

Nothing is more discouraging than reading an article and then realizing that you do not know what you read. A similar frustration arises when you are trying to follow directions on assembling a toy, particularly when the instructions read, "... even a 5-year-old can assemble this toy," and you cannot do it, because the directions read as if they were written in a foreign language. Assume that if there is any chance of misunderstanding, readers will misunderstand. Reread what you have written looking for points that could lead to readers' misunderstanding.

COHERENCE

An article that skips illogically from topic to topic and back again in a jumbled, befuddled manner lacks coherence. Coherence means sticking together, and that is what stories and articles should do. Facts should follow facts in some kind of reasonable order. It may be logical order, chronological order, place order or order of importance, depending on the subject, but order of one kind or another is vital. Outlining will often help.

EMPHASIS

Make sure your writing emphasizes what you want it to. You assure this in newswriting by putting the most important fact first (the lead, discussed later).

Other types of arrangements for emphasis are used in feature stories or in editorials and will be presented later in this chapter.

OBJECTIVITY

To report news accurately, you must keep yourself detached from the happenings and present an impersonal, unbiased, unprejudiced story. This is why you never see a good reporter at an accident running around saying, "Isn't this horrible? I feel so sorry for the family. Why, just the other day I was talking to ol' Jed, and now he is dead." These may very well be your feelings, but you must attempt to keep aloof to give an objective report. It is not your job to influence people directly, but rather to tell them what is going on. You direct their thinking only to the limited extent that you make them think for themselves by an unbiased presentation of the facts.

UNITY

A news story should deal with one basic topic. There may be many facts and ins and outs to the story, but it is still one story. If you set out to write a story on the services and activities available at the enlisted club, and end up with a biography of the club manager, the story lacks unity. The simple solution frequently is to write two stories, rather than trying to combine a mass amount of information into one.

THE LANGUAGE OF NEWSWRITING

Written language is made up of three elements—**words, sentences and paragraphs**. It is the way these elements are handled that makes the difference between literary and news English. Briefly, let us look at these elements separately.

Words

Words are your basic tools. Like any skilled technician, you should be able to select the best tools to do the best job. This means you should use words that say exactly what you mean so others can understand them.

Every word used in a news story should add to the picture you are building in the minds of your readers. If

you use an unnecessary, vague, or unfamiliar word, this picture becomes blurred. If it becomes too blurred, it may give the reader a distorted picture of the facts. This is a form of inaccuracy that is just as bad as putting the wrong facts down on paper.

It is an axiom of newswriting that words that do not work for you, work against you. Here are a few tips on making words work for you.

AVOID GOBBLEDYGOOK.—Gobbledygook is confusing writing, often marked by pseudotechnical language that readers cannot understand. In writing a technical story, do not parrot the words some technical-minded researcher pours out. **Simplify.** Ask, “What does this mean in everyday English?” Few people, for example, know what “arteriosclerosis” means. But when you say “hardening of the arteries,” they immediately understand.

AVOID WORDINESS.—Many inexperienced writers put unnecessary words into their news copy. Call a spade a spade, not “a long-handled agricultural implement utilized for the purpose of dislodging the earth’s crust.”

Short, common words are easy to understand when, in many cases, long words are not. If you must use a longer word, make sure you are using it to convey a special meaning, not just for the sake of using a big word. Why use **contribute or provided with** if **give** means the same thing? This also applies to **veracity** for **truth**, **monumental** for **big**, **apprehension** for **fear**, **canine** for **dog** and countless others. Practically every part of speech contains long words that may be replaced by shorter and more exact ones. The same principle applies to phrases. Why say “afforded an opportunity” when “allowed” is more exact, or why use “due to the fact that” instead of “because”?

BE SPECIFIC.—Inexactness is just as bad as wordiness. Readers want to know specific facts. Consider the following example of this:

Vague: Thousands of fans were turned away that afternoon.

Specific: Three thousand fans were turned away before game time.

AVOID TRITE OR HACKNEYED EXPRESSIONS.—Trite or hackneyed expressions are the mark of either an amateur or a lazy writer. Some particularly bad examples include the following:

- Cheap as dirt

- Smart as a whip
- Fat as a pig
- Nipped in the bud
- Good as gold
- Blushing bride
- Grim reaper
- Wee hours
- Ripe old age
- Picture of health
- Crystal clear
- Quick as lightning
- Bouncing baby boy/girl

USE STRONG, ACTIVE VERBS.—Whenever possible, use active voice and the simple past tense. The use of these injects life, action and movement into your news stories. In using strong verbs, you will find some of the tendency for you to rely on adverbs to do the work is eliminated. In newswriting, adverbs often do nothing more than clutter writing. Consider the following example:

- **Weak** (passive voice): The visitors were warmly received by Captian Smith in his office.
- **Stronger** (active voice): Captian Smith greeted the visitors in his office.

AVOID MILITARY JARGON.—For those in the Navy, the phrase “general quarters” is clear enough. Yet for others, the phrase may mean nothing; to some, it may seem to mean the area where the general is housed. When you assume that all your readers know general quarters means the command to man battle stations for crew members aboard ship, you make a false assumption. You do not impress your readers by using words and phrases they do not understand; you only irritate them.

For example, an unidentified Navy official issued a statement explaining that the purpose of an overtime policy was “... to accommodate needs for overtime which are identified as a result of the initiation of the procedures contained herein during the period of time necessary to institute alternative procedures to meet the identified need.”

In some situations, it is appropriate to use common military phrases, such as “fleet training exercise,” “ship’s galley,” and “weapons system.”

WATCH SPELLING AND GRAMMAR.—A JO, or a person interested in becoming a Navy Journalist, should have better than average spelling ability. This person should also have a good command of the English language as far as correct grammar is concerned. Therefore, no extensive lesson is given in this area of study, although some basics are presented in chapter 6.

One goal of every good writer is not to learn to spell perfectly, but to learn to spell well enough so that a mistake can be spotted when words are put on paper. When in doubt, use the dictionary. Dictionaries are standard stock items in the Navy, and every public affairs office should have one. (For style, usage and spelling questions not covered in *The Associated Press Stylebook and Libel Manual*, use *Webster's New World Dictionary of the American Language, Third College Edition*.) Additionally, keep in mind that virtually all word processing software packages contain a spell check feature that you should use at every opportunity.

USE A STYLEBOOK.—In newswriting, the word **style** refers to the spelling, punctuation, capitalization, abbreviation and similar mechanical aspects of grammar used in preparing copy (a term used to describe all news manuscripts). Most newspapers and other periodicals have their own style sheets or local interpretations of style rules. The important thing for you to remember about style is **consistency**.

The recommended guide for preparing military news is *The Associated Press Stylebook and Libel Manual*. However, any locally prepared style guide or style sheet is fine as long as it is internally consistent and is suitable for your purpose. For further information on stylebooks, consult chapter 7 ("Newspaper Staff Supervision") of the *JO 1&C* NRTC.

Sentences

The second element of language is the sentence. The simple declarative sentence that consists of subject and verb, or subject, verb and object is the most common form in normal, informal conversation. For this reason, it is the best sentence structure for most newswriting. Notice how the following sentence becomes more readable and understandable when it is rewritten in two simple sentences:

Sentence: Following his graduation from the U.S. Naval Academy in 1948, Brown was assigned to the destroyer USS *Roulston*, where

he served his first tour of sea duty for 3 years as assistant communications officer and junior watch officer.

Rewrite: Brown graduated from the U.S. Naval Academy in 1948. He spent his first tour of sea duty aboard the destroyer USS *Roulston* as assistant communications officer and junior watch officer.

Simplifying sentences is not difficult, but it does take a little practice. In time, you can learn to use just the right number of words to achieve maximum clarity without destroying smoothness.

There are no absolute rules, but a fair guide is to try to keep sentences to 30 words or less and to shoot for 17 to 20. Vary the length of your sentences. For example, you might use a four-word sentence, then a 15-word sentence, and then an eight-word sentence, followed by a 30-word sentence. This keeps your writing from becoming singsong.

DO NOT CLUTTER.—Never crowd too many details into one sentence. Although a compound or complex sentence may contain more than one thought, you should, for the most part, stick to sentences that express one thought clearly and concisely. Otherwise, the reader is apt to get lost in a mass of clauses and details.

DO NOT REPEAT.—If you say in the lead of your story that 61 people were killed in a training accident, do not mention later in the story that 61 were killed. If the readers forget a fact, they can look back. Newspaper space is valuable; do not waste it with redundancy. Refrain from beginning a sentence with the same word as the last word in the previous sentence and avoid beginning consecutive sentences alike, unless you do it deliberately for emphasis.

Paragraphs

The most general guideline for writing paragraphs is that they should be kept reasonably short. When you use short paragraphs, you give the reader facts and ideas in smaller packages that are easier to handle. The mind can grasp a small unit of thought more easily than a large unit. Also, most news copy is set in narrow columns with only three to five words per line. This makes paragraphs of normal literary length appear as extremely long, unrelieved gray blocks of body type (more detail on typography, the appearance and arrangement of printed matter is contained in chapter 8). These large gray blocks of type are monotonous to the reader's eye and difficult to read.

Paragraphs should be less than 60 words. Two or three sentences per paragraph are just about right, but it is perfectly acceptable to have a one-sentence paragraph, or even a one-word paragraph, if it expresses a complete thought.

Yet, a succession of very short paragraphs may give a choppy effect to the writing. For best effect, alternate paragraphs of short and medium length. Never begin succeeding paragraphs with the same words or phrases. This, too, can cause a monotonous effect that will soon discourage the reader.

THE STRAIGHT NEWS STORY

LEARNING OBJECTIVE: *Outline the various parts of the straight news story.*

The major difference in style between newswriting English and literary English was discussed earlier in this chapter. There is also a big difference in structure between the literary piece and a newspaper story.

Journalism and architecture have more in common than what is evident at first glance. While the designing and planning of a building is far more complicated than the construction of news story, both are the same in principle. In each case, space is a prime element.

An architect uses bricks, cement and other materials; a newswriter uses words as his bricks and cement. If the building lacks design and careful construction, it will collapse; if the news story is not carefully planned, it will only serve to confuse the reader and discredit the publication in which it appears.

Before you can present the facts, you first must understand them, appraise them correctly and organize them in an orderly and easily understood manner. This process of organization and selection begins when you set out on an assignment. You rarely will be able to get your facts in the order in which they will appear in the final story. The process of legible note taking provides the raw material for you to construct the story, and certain proved guidelines serve as the blueprint for building the final product.

In fiction, a short story or novel is normally constructed in chronological order. This means the author starts from the beginning, sets the time and place, describes the scene, introduces his characters, then slowly weaves the threads of his plots and subplots until a climax is reached, usually near the end

of the story. The writer deliberately holds back the climax to build suspense and to make sure the reader reads the entire story.

Most news stories, however, are constructed in just the opposite fashion. **The climax is presented first.** This method packs the most important facts together with the barest necessary explanatory material into the first paragraph (the summary lead), then moves into the detailed portion of the story (the body) by covering the facts in diminishing order of importance. This form of newswriting is commonly known as the **inverted pyramid** style because when it is diagrammed, it appears as an upside-down pyramid (fig. 2-2).

ADVANTAGES OF THE INVERTED PYRAMID STYLE

The inverted pyramid style offers several distinct advantages in newswriting, which are discussed in the following text.

Presents Pertinent Facts First

Most readers have neither the time nor the desire to read every word of every story in a newspaper. By using the summary lead, the JO focuses the reader's attention on the news, arouses the reader's interest and allows the reader to swiftly skim important facts. In other words, spill the whole story in the first paragraph.

Figure 2-2.—Inverted pyramid news story structure.

The reader can decide whether to continue reading the details or to go on to something else. But even if the reader stops there, the inverted pyramid form of writing has provided the essential facts. The primary objective of a news story then, is not to withhold information, but to present the facts with rapid, simple directness.

Facilitates Page Layout

The inverted pyramid method of story construction is a valuable tool to the makeup person who is confronted with an eight-inch story and only six inches of column space. If the story has been written in inverted pyramid form, it becomes a simple matter of cutting lines of type from the bottom of the story until it fits the available space or “jumping” (continuing) the story on another page—all without damage to the important facts that appear at the top.

Facilitates Headline Writing

Headlines for news stories should tell the main facts in the briefest form. If a story is written in the proper inverted pyramid style, the copyreader (who writes the headline) can find these facts in the first paragraph. The copyreader will not have to search the entire story for headline material.

THE LEAD

The opening paragraph of a news story is referred to as the **lead** (pronounced “leed”).

The lead is the first and most important paragraph of any news story. It attracts the reader and states the important facts first.

A key fundamental fact taught in classrooms the first time newswriting is mentioned, and repeated at the college level, is that in writing a lead for a straight news story, the writer must answer six basic questions about the event. Known as the five Ws and H questions, they are as follows: **who**, **what**, **when**, **where**, **why** and **how**.

It is not necessary that a writer answer all of these questions in the lead sentence. The summary lead does, however, attempt to answer several of the more important ones. To insist upon answering the five Ws and H questions as a rigid format will lead to lengthy, cumbersome leads that may be misleading or hard to read. The lead contains the news peg and is the most important part of the story. It can either make or break any news story.

Length

Try not to use more than 30 words in the lead, but do not make this an inviolable rule. Some leads, even when well written, may require 35 or even 40 words. On the other hand, many—or perhaps most—require fewer than 30 words to accomplish their objective.

A good lead may be a single word, a single sentence, two sentences, a paragraph or even two paragraphs. Whatever form it takes, it must answer the questions a reader would normally ask such as the following: “**What** has happened or is about to happen?” “**Who** is involved?” “**When** and **where** did it happen?” And, sometimes, “**how** and **why** did it happen?” An effective lead directs the reader’s interest into the body of the story.

The summary news lead is the one most often used at the beginning of a straight news story. The most direct approach (and best method for an inexperienced writer to use in constructing a summary lead) is known simply as featuring the most important element. Featuring the most important element means exactly what it says. The writer determines which of the five W’s and H is most important to the story and places it at the outset of the lead. Each of the example leads in table 2-3 features a different W or H as the most important element.

The leads in the figure are given to show how any element may be featured. The “why” element (to prevent a forest fire in this case) is clearly understood and can be dropped out of most leads to avoid redundancy and extra wording. Other summary lead examples are presented in table 2-4 that answers all or most of the necessary five W’s or H. Those omitted are either implied or unnecessary.

The five summary lead examples in table 2-4 are all “who” leads. In each example, who is featured at the beginning of the lead, thus giving it more prominence than the other W’s or H. More examples of summary leads are illustrated in table 2-5, with a different W, or H, featured at the beginning of each.

Feature and Novelty Leads

Although the summary lead is the simplest, safest and strongest of all leads used in straight newswriting, most media like to add a little variety when leading into a story. Feature leads are a vital part of newspaper writing. The feature lead permits you to take a mundane straight news piece and transform it into a

Table 2-3.—Example Lead Variations

Element	Example
Who	A smoke jumper extinguished a blaze and prevented a forest fire in Gallatin National Forest, Wyo., yesterday by diverting a mountain waterfall over a burning tree. Note: This is an impersonal “who” lead. The “who” can be identified in general terms when the individual or group is not well known by name, such as “three Navy admirals,” “a former secretary of the Navy,” or “three Navy seamen.” When the impersonal “who” lead is used, the actual name or names should be mentioned further down in the story.
What	A burning tree didn’t become a forest fire in Gallatin National Forest, Wyo., yesterday because a smoke jumper diverted a small mountain waterfall.
When	Yesterday a smoke jumper prevented a forest fire in Gallatin National Forest, Wyo., when he diverted a small mountain waterfall over a blazing tree.
Where	In Gallatin National Forest, Wyo., a smoke jumper yesterday prevented a forest fire by diverting a small mountain waterfall over a burning tree.
Why	To prevent a forest fire in Gallatin National Forest, Wyo., a smoke jumper yesterday diverted a small mountain waterfall over a blazing tree.
How	By diverting a small mountain waterfall over a blazing tree in Gallatin National Forest, Wyo., yesterday, a smoke jumper prevented a forest fire.

story that captures the interest and empathy of the readers.

Novelty leads differ from summary leads in that they make no attempt to answer all of the five W’s and the H. As the name implies, novelty leads are **novel**. They use different writing approaches to present different news situations to attract the reader’s attention and arouse curiosity.

Feature leads must fit the mood of the story. If you intend to set a particular mood or point of view in a story, your intent or tone should be set at the beginning of the story.

If the situation presents itself in which a novelty lead would be appropriate, by all means use it. Do not get into the habit, however, of trying to write a novelty lead for every story, because they are not always adaptable to every situation. It is easy for the unusual to become commonplace if it is seen or heard too often. Novelty leads lose their effect if they are overused.

Table 2-6 presents various examples of novelty leads most commonly used in news writing. Although the eight types described are the ones most commonly used, it is a mistake for you to assume that all news leads may be categorized by type or classification.

Their names are not important anyway. To the JO, the ability to write is more important than the ability to categorize.

Identity and Authority

There are two other considerations to keep in mind when you are preparing news leads — **identity** and **authority**. In most local stories, especially hometowners, it is necessary to identify persons fully in the lead.

For example, suppose you prepared a hometown story on a Sailor who formerly resided in Louisville, KY. Not being very experienced, you turn in a lead like the following:

“Navy Seaman Walter T. Door reported for duty Feb. 16 aboard the guided-missile cruiser USS *Hinkle*, now operating in Western Pacific waters.”

Although you have answered all the W’s and the H, except why and how (in this case unnecessary), your lead is still incomplete. The story is meaningless until you identify Door as being from Louisville. Even then, an editor of a Louisville newspaper will want a local angle on the Sailor. The only angle available to you is the name of Door’s parents and their home address.

Table 2-4.—Example summary leads by story category

Story Category	Summary Lead
Hometownner	<p>WHO AT SEA ABOARD USS <i>KITTY HAWK</i> —Seaman A.B. Jones, son of Mr. and Mrs. A.C. Jones of Route 1, Fayetteville, Tenn.</p> <p>WHAT reported for duty</p> <p>WHEN July 25</p> <p>WHERE aboard the aircraft carrier USS <i>Kitty Hawk</i>.</p>
Award Presentation	<p>WHO AGANA, GUAM — A Navy petty officer</p> <p>WHAT was awarded the Navy Marine Corps Achievement Medal</p> <p>WHERE here</p> <p>WHEN today</p> <p>WHY for saving the life of a 5 year-old girl</p> <p>HOW by rescuing her from the shark-infested waters of Telefofo Bay.</p>
Accident Story	<p>WHO NORFOLK, Va., Jan 7 — A Navy seaman</p> <p>WHAT was killed</p> <p>WHEN today</p> <p>WHY when his car collided with a bus</p> <p>WHERE near Wards Corner on Granby Street.</p>
Change of Command Story	<p>WHO SAN DIEGO – Captian Able A. Boate, USN,</p> <p>WHAT took command of the submarine tender USS <i>McKee</i> (AS 41)</p> <p>WHEN today</p> <p>WHERE in shipboard ceremonies at North Island.</p>
Convention Story	<p>WHO NAS ALAMEDA, Ca. — Forty-five members of the famed “Doolittle Raiders”</p> <p>WHERE were present here</p> <p>WHEN this week</p> <p>WHAT for a three-day program which commemorated the 50th anniversary of the first American bombing raid on Japan.</p>

You must, therefore, identify Door more fully in your lead. It is unlikely that many of the newspaper's readers would know him merely by name, and a city the size of Louisville might have more than one Walter T. Door. To localize the story and to avoid confusion or misinterpretation, you would include more

identification. The lead should be written in the following way:

“A Kentucky native, Seaman Walter T. Door, son of Mr. and Mrs. Mack Door of 70 N. Williams St., Louisville, reported for duty Feb. 16 aboard the

Table 2-5—Sample summary leads featuring the most important elements

Dominant Fact	Lead Example
WHEN: Sometimes the time element plays an important part in the story.	With only five seconds left to play, Navy scored the winning touchdown to defeat Army, 36-30 in the annual football classic this afternoon in Philadelphia.
WHERE: If the setting of your story is unusual or especially important, play it up at the beginning.	Three hundred miles above the earth's atmosphere, two Navy astronauts are orbiting the earth in a spacecraft at speeds more than 50 thousand mph.
WHAT: When a thing or action in a story is noteworthy and overshadows the other facts, it, too, should be featured in the beginning.	Bowling two consecutive 300 games was the unprecedented accomplishment of Dick Hitchens, USN, a crew member of the submarine tender USS <i>Milano</i> .
WHY: The motive, cause or reason may also be an important feature of the lead.	Because he was raised in an orphanage himself, a veteran Navy combat pilot is attempting to adopt two Italian children whose parents were killed in an automobile accident.
HOW: The circumstances or the manner in which something is accomplished in a news story is often important.	By hurling a 20mm shell magazine from the destroyer USS <i>Homeboy</i> yesterday, a Navy gunner's mate prevented severe damage to his ship and possibly saved the lives of several crewmembers.

guided-missile cruiser USS *Hinkle*, a unit of the Navy's Seventh Fleet in the Pacific."

As you can see, complete identification of a person in the lead sometimes makes that lead long and cumbersome. Yet, it cannot be avoided in hometown stories where identity is more important than the action, especially if the action is weak, as it is in the preceding example.

In many instances, however, full identification is unnecessary or impractical for inclusion in the lead. In general, complete lead identification is unnecessary and should be avoided when one or more of the following points is true:

- The action overshadows the person or persons involved.
- There are too many persons involved to identify all of them by name and rate.
- The identification does not mean much to the readers in a particular area.
- The "who" is a prominent, widely known person.

When an individual is not fully identified in the lead, that person must be identified by name, rank or rating, title, duty station and possibly hometown address elsewhere in the story. This identification is also important for places and things in a story. If you use the name of an unfamiliar town or city in a story, at least identify it by the state in which it is located. If you use the name of a ship or an airplane, give its type or classification.

Impersonal identification may be used in the lead when the news subject consists of several persons unfamiliar to the reader, such as groups or organizations. Nonspecific what's, where's, and when's may also be used depending on the news circumstances.

Authority is the source from which quotes and information originate in a story. Like identity, it should be used in the lead only when necessary. Never use authority in a story when the source of information is clearly implied.

The following is an example of a lead in which authority is necessary:

Longer tours, fewer, shorter and less expensive moves can all be expected by Navy

Table 2-6.—Sample Novelty Leads

Type of Novelty Lead	Example
<p>CONTRAST: The contrast lead compares two opposite extremes, generally to dramatize a story. The comparisons most frequently used are tragedy with comedy, age with youth, the past with the present and the beautiful with the ugly.</p>	<p>In 1914, the United States entered the First World War with a Navy of 4,376 officers, 69,680 men, 54 airplanes, one airship, three balloons and one air station.</p> <p>Today, there are more than 500,000 active-duty officers and enlisted personnel, 475 ships and 8,260 aircraft in our Navy.</p>
<p>PICTURE: The picture lead draws a vivid word picture of the person or thing in the story. It allows the reader to see the person or thing as you saw it.</p>	<p>Thin and unshaven, his clothes drooping from his body like rags on a scarecrow, Lt Frank Brown, USN, today told naval authorities about his six-week ordeal in an open rubber boat in the South China Sea.</p>
<p>BACK GROUND: The background lead is similar to a picture lead, except for one important difference. It draws a vivid word picture of the news setting, surroundings or circumstances.</p>	<p>High seas, skies, strong winds and heavy overcast provided the setting for a dramatic mission of mercy in the North Atlantic on the first day of the new year.</p>
<p>PUNCH: The punch lead consists of a blunt, explosive statement designed to surprise or jolt the reader.</p>	<p>The president is dead. Friday the 13th is over, but the casualty list is still growing.</p>
<p>QUESTION: The question lead features a pertinent query that arouses the readers' curiosity and makes them want to read the body of the story for answers. Phrase this lead as a rhetorical question (a question that cannot be answered with a straight "yes" or "no").</p>	<p>How does pay in the Navy compare with civilian wages?</p> <p>Has the space age affected the role of the Navy?</p>
<p>QUOTATION: The quotation lead features a short, eye-catching quote or remark, usually set in quotation marks. A quote lead should be used only when it is so important or remarkable that it overshadows the other facts in the story.</p>	<p>"You really don't know what freedom is until you have had to escape from Communist captivity," says Bob Dengler, a former Navy lieutenant and an escapee from a Viet Cong prison camp.</p>
<p>DIRECT ADDRESS: The direct address lead is aimed directly at the readers and makes them collaborators with facts in the story. It usually employs the pronouns "you" and "your."</p>	<p>Your pay will increase by 10 percent next month. You can receive a college education at Navy expense if you qualify under a new program announced this week.</p>

people for the rest of this fiscal year, according to Vice Adm. Jack Frost, Chief of Naval Personnel.

Attributing this statement to the Chief of Naval Personnel gives it authority, because the admiral is in a position to know and speak about such matters.

Contrary to popular belief, people do not believe “everything” they read in newspapers. Many of them, as a matter of fact, challenge any statement that conflicts with their preconceived opinions. Using authority in a story helps you overcome this natural skepticism. Sometimes people will believe certain facts more readily if they know or respect the person to whom they are attributed.

What follows are two simple rules governing the use of authority in a news story:

- Use it when it appears that the reader may challenge a statement.
- Use it when the name of the authority lends support or emphasis to the facts.

In the Navy, the authority for many statements is frequently implied. If a story obviously deals with Navy ships, Navy personnel or Navy equipment, it is often unnecessary to use “The Navy announced today” or similar expressions. If a newspaper editor feels a statement must be attributed to the Navy, the editor will insert the authoritative source. It is a bad practice for this phrase to be inserted in every story merely for the sake of using it or just to get the word “Navy” into the story. It is also particularly bad for every news release to be attributed to the captain or admiral by name, especially when the subject of the story is remote from his immediate interest.

For a wrap-up on preparing the lead, you should keep the following four objectives in mind:

- Present a summary of the story
- Identify persons and places involved
- Stress the news peg
- Stimulate the reader to continue reading the story

THE BRIDGE

Assuming you have written the lead for a story, what do you do next? In some stories, you will find the transition from the lead to the body of the story is a bit awkward. To smooth this transition, you use a writing device known as a **bridge**.

A bridge is a connecting sentence or paragraph between the lead and the body of the story. Although it is not always required, it can serve several useful purposes. For instance, in the bridge, you can place facts that are too detailed for the lead and too important

to be placed lower in the story. Note the following example:

Novelty Lead: For sale: One guided missile destroyer.

Bridge: The Navy is thinking about inserting this advertisement in the nation’s newspapers. The guided missile destroyer USS *Benjamin Stoddert*, which is no longer fit for active service, will be scrapped next month.

Note that the writer used a freak lead to introduce his story. The entire lead consists of only six words, and the effect is good. The lead obviously would not be as effective if all the facts were presented in the first paragraph.

A bridge also can bring the reader up to date on past and present events related to the story by the use of **tie-backs** and **tie-ins**.

Tie-Back

A tie-back is a newswriting device that allows you to refresh the reader’s memory about past events related to the story being written. It frequently is used in follow-up stories (see chapter 5). Consider the example that follows:

Lead: The U.S. Coast Guard icebreaker *Northwind*, with the help of U.S. icebreakers *Glacier*, *Staten Island* and the Canadian icebreaker *MacDonald* is free from the arctic ice pack that threatened to maroon the ship until next summer.

Bridge (used as a tie-back): *Northwind* was making the trip back from an attempt to resupply the research station ice-island T-3 when it began experiencing difficulties maneuvering through the polar ice. The ice was so severe the ship lost a blade on its starboard propeller and cracked the ship’s hull.

Body: The relief ships punched their way through. ...

Tie-In

A tie-in is similar to a tie-back, except it provides information concerning **other** events that are currently taking place and that supplement the story being written. While the tie-back deals with the past, the

tie-in deals with present events. Consider the following example:

Lead: Navy doctors are investigating an outbreak of 17 cases of scarlet fever aboard the destroyer USS *Balast*, a Norfolk-based ship operating in the Mediterranean.

Bridge (used as a tie-in): Meanwhile, measures are being taken to prevent further outbreaks of the disease on other Navy ships. Navy personnel have been warned to report to shipboard sick bays immediately if they find themselves suffering from fever, sore throat or rashes on the neck and upper chest.

Body: The first case of scarlet fever was reported aboard the *Balast* April 27, about three weeks after the ship left Norfolk. Doctors said....

The tie-in can explain or elaborate on one or more of the summary facts, usually why or how. In writing a summary lead, you may find that it becomes long and unwieldy if you try to include a detailed explanation of why and how. But if the explanation is important enough, instead of withholding it until the body of the story, present it in the bridge as in the example that follows:

Summary Lead: The Navy will begin replacing its time-tested manila lines July 1 with a synthetic product of modern progress—nylon rope.

Bridge (explaining “why”): After months of study and experimentation, the Ship’s Systems Command has found that nylon rope is superior to manila line in strength, durability and elasticity.

If you have to include the information from these two sentences in your lead, it would become unnecessarily long and cumbersome. By explaining the why in the bridge, you present the information more clearly and make the story more readable. It can provide continuity and a smooth transition from the lead to the body of the story by bringing in one or more secondary, but significant, facts. Note the following example:

Lead: From now on, all of the accounting for the Navy’s vast network of ship’s stores will go untouched by human hands.

Bridge: CompuNav, an electronic data processing system, will do the job—and do it cheaper too.

Body: The CompuNav file computer was unveiled today. ...

The bridge in this story is strictly a transitional device that helps close the gap between the lead and the body of the story. Reread these sentences again. Note how awkward the story would be if the bridge were omitted.

THE BODY

For you to produce a smooth, final story, the lead and body must coincide. The body is the detailed portion of a news story that develops and explains the facts outlined in the lead (and in the bridge, if there is a bridge). Here again, the importance of a neatly tailored lead cannot be overemphasized. A cumbersome lead is most often followed by a cumbersome body. But when a lead has done its job, it will usually provide an outline for the orderly organization of facts in the body of the story.

To some extent the organization of the body is dictated by the material itself—if it is a series of events, for instance. So the writer has to write an orderly, well-organized story and at the same time keep in mind the relative importance of various details.

Guided by the idea of news importance, the writer proceeds through the story by selecting the next most important incident, fact or detail, then the next important, and so on, until reaching the least important of all. At this point, the writer has reached the apex of the inverted pyramid with material of least value. The writer now knows that the makeup editor can slice one, two, or three paragraphs from the bottom of his story without depriving the reader of the story’s chief news elements. Table 2-7 shows a diagram of a straight news story structure.

A FINAL THOUGHT

For several years, there has been a trend among civilian newspapers toward greater informality in news presentation. This trend has become known as “talking a story onto paper.”

Several years ago, an observant editor noticed that a reporter would come to the city desk and describe a story he has covered. The story would sound attractive as he talked. Then the same writer would go to his desk and write the piece, pouring facts into the established newswriting mold. What had been interesting when he related it verbally, it then sounded like every other

Table 2-7.—Diagram of a Straight News Story

SUMMARY LEAD	EGLIN AFB, FLA (NNS)—A Navy officer who had never before taken control of an aircraft brought an Air Force spotter plane in for a rough but-successful-landing recently.
FACT 1 (bridge)	The incident came about after the pilot Navy Lt. Fred Johnson, 28, died of a heart attack during a routine training mission over the Gulf of Mexico.
FACT 2	LT John G. Smith, USN, of Aurora, Ill., walked away from the emergency landing only “slightly shaken up.” The incident occurred in an area 60 miles southwest of Eglin Air Force Base.
FACT 3	Smith took control of the single-engine plane and returned the aircraft to Eglin.
FACT 4	Presently assigned to Eglin as a Navy liaison officer, Smith reported to his present duty station last July.
FACT 5	A former enlisted man, the 39-year-old officer served as an aerial photographer for several years and his general familiarity with aircraft is credited with helping him land the plane.

story that had appeared before—only the names and places were changed.

Recognizing the value of the reporter’s conversational report of the story, the editor thereafter encouraged his writers to use a more conversational tone, coupled with simple language, in all of their copy.

The main purpose of any news story is to **communicate the facts**. To accomplish this communication, individuals must read the story. When an informal story presented in simple, everyday language can accomplish this purpose, use it without hesitation.

CHAPTER 3

WRITING THE FEATURE, SPEECH, SPORTS AND ACCIDENT STORIES

In chapter 2, the fundamental aspects of newswriting were covered. Once you master the basics of newswriting, then, and only then, are you ready to wrestle with the more complex news stories. This chapter will help you develop the skills and learn the knowledge necessary to write effective feature, speech, sports and accident stories.

THE FEATURE STORY

LEARNING OBJECTIVE: *Identify the characteristics and structure of a feature story and the techniques used in producing a personality feature.*

Writing straight news strengthens the writer's powers of observation and builds his skill in using the English language. It impresses on the writer the necessity for ruthless editing until the story is specific, clear and vital.

Conversely, feature writing is not an exact science. Much depends on the skill, imagination and creativeness of the writer.

What is a feature story? It has been called the story that "has to be told." It has also been called simply "human interest." Interest in human beings, and in events because they concern people in situations that might confront anyone else, is called human interest. When a shipboard explosion takes the lives of several crew members and prompts the gallant efforts of other crew members to prevent the loss of the entire crew, the human interest, or appeal, may be of a sympathetic nature. A man with a broken nose might also evoke a sympathetic response. However, if the injury occurred when he walked into a telephone pole while scrutinizing an attractive 1957 Chevrolet on the other side of the street, the appeal might be of a humorous nature.

Certain topics have human interest built in. And, although they may not possess any of the other elements of news value (timeliness, proximity, prominence or

Figure 3-1. Feature story photo. U.S. Navy photo

consequence), they still have personal appeal (fig. 3-1). Human interest may fall into many categories, including those in the following list:

- Current topics
- The unusual and the extraordinary
- Mysteries and catastrophes
- Romance and sex
- Adventure and exploits
- Competitive contests
- Child, teenage and adult life
- Animal life
- Recreation and hobbies
- Business, professional and home activities
- Social welfare
- Success and happiness

In any case, a good human interest story is built around the premise that the reader can easily identify with the subject or event. It involves a fellow human being and a situation that could happen to, or involve, the reader.

Human interest stories not only entertain, but are often informative in that they contain all the elements of a news story. However, the human interest aspect of the story outweighs its value as a straight news story.

Major news events seem to tell themselves. The straight newswriter can set down all the facts, arrange them together with appropriate words and have an adequate news story. The feature, however, must be brought to public attention by the creative writer. As a Navy JO, your job is to recognize the human interest possibilities of stories and turn a drab yarn into a bright one without exaggeration or distortion.

CONTENT

The feature story is similar to basic news writing in that it has a news peg. What sets it far apart, however, is that it emphasizes something new, odd or unusual. Both of these attributes are covered in the following text (fig 3-2).

News Peg

The Cuban Missile Crisis of 1962 was an event with intense, hard news value. Confrontation between the two strongest world powers could have been the lead paragraph on the story of World War III. Events in this confrontation made the news wires sing for many weeks.

When the USS *Norfolk* intercepted a Russian ship removing missiles from Cuba, the New York Times News Service covered it in a lead that read as follows:

The captain of a Soviet freighter reluctantly stripped the tarpaulin covers from eight medium-range missiles on the deck of his

freighter Friday for photographing by a United States destroyer.

Using this news event as a peg, and realizing that he could not compete with news-service speed in making releases, the PAO aboard *Norfolk* released a feature with a different slant:

Much of the old-style drama and military dash of the international crisis is a thing of the past. The thrill of “Victory at Sea” is no longer as graphic in its modern context as that famous World War II documentary movie.

Today’s coverage of events that shape the lives of nations comes, often as not, from the centers of government and military command posts. For the chess game of world events is no longer played in the smoke of battle, but in planning rooms where statesmen, military personnel and civilians in government call the plays thousands of miles from the scene of the move. ...

New, Odd or Unusual

The event and object sources are rich in feature prospects. Here, the imagination and curiosity of the writer are put to the test. Most hobbies are quite commonplace, yet an ordinary hobby can provide good story material if there is an element of the **new**, the **odd** or the **unusual** connected with it.

In conjunction with hobbies and collections, museums supply fine material for stories. Here the ideas usually come from historical circumstances surrounding the objects of their development. Browse through a museum and ask yourself these questions: Why is this object on display? What significance does it have? What historical event is connected with it?

Stories concerning historical events must be especially well-written and interesting because people do not like to read about events presented in textbook style. However, they are interested in what one person or group did in a particular historical event.

These are a few common areas that produce ideas for articles. There are many others. The point is, the ideas are there and you must open your eyes to them.

REQUIRED FEATURE WRITING SKILLS

To become a successful feature story writer, you must be proficient in the following feature writing skills: grabbing the reader’s interest, being observant

Figure 3-2. Stand-alone feature photo.
(Photo by PH2 Erin A. Zocco)

and writing about people. These areas are examined in the following text.

Grabbing Reader Interest

To attain reader interest, features may depend on prominence such as that in an event like the Cuban Missile Crisis. The personality profile would also fit here. And, in this case, the relationship between the news elements of proximity and prominence should be considered. For example, a story about one of the space shuttle crew members would be of interest almost anywhere because of the prominence of the subject. How about the CO of Anderson Air Force Base, Guam? The proximity to Anderson AFB and surrounding communities might make the CO prominent enough to merit a personality sketch in the local Guamanian newspaper, but nowhere else, except perhaps, his hometown.

Consideration for the target readership, then, is important for the writer of feature articles. It soon becomes obvious that attempts to define a feature story fall short, probably because the range of material is as broad as the full range of human experience. Anything people make, do, enjoy or respond to serves as a peg on which to hang the feature story.

Feature stories stir emotions, stimulate, divert and entertain. These objectives could serve as a goal for the feature writer, but they do not tell what feature stories are. Certainly, the account of one nation's warship intercepting the missile-carrying freighter of another in international waters is capable of stirring emotions and stimulating readers of the world.

The story behind the story—the feature story—is the vehicle for unabashed revelation of the human interest element in any hard news event. The PAO's Cuban missile feature does this as it continues:

The Cuban Quarantine centers the eye of the world on the Caribbean, while the real events are charted far away in Washington and Moscow. The drama of confrontation is still very much set in scenes of ships patrolling the seas around Cuba. The lines of battle are drawn by ships every bit as powerful, many times as sophisticated, and just as serious as the battleship behemoths of former wars.

When the forces meet, as when the destroyer leader USS *Norfolk* (DL 1) detected the Russian merchantman *Leninsky Kosomol* steaming out of the south Cuban port of

Casilda through the receding clouds of a tropical rainstorm, the surface action begins with the flashing light of exchanging calls.

Events followed rapidly as the radio waves emanating from the two ships pulsed messages reporting contact and requesting instructions. Agreements between governments born at United Nations sessions began to be implemented on the high seas. ...

Being Observant

The successful and prolific feature writer develops a keen, inquisitive faculty for observation. A well-tended landscape is not just a pleasant view to the feature writer. The journalist wonders who keeps it trim and why, inquires into the benefits of conservation or erosion control and the alternatives—wildlife sanctuaries or outdoor living. And chances are, the writer can write the answers received into an interesting feature article.

The power of observation, the habit of accepting nothing at face value, of digging into unanswered questions below the surface of the event, are invaluable to the feature writer.

A prime source of ideas is the daily newspaper. News stories that appear in the newspapers record national, state and local events as they happen. They usually do not give background material or cover all aspects of a story. Yet every day, news stories appear that open the way for a flood of feature articles.

The ability to take a bare fact from the newspaper and give it meaning can produce a good article, but here, as in wire service copy, the feature must reflect **local** interest. For example, a news story mentions a change in income tax regulations; the feature writer shows how this change will affect the reader. Thus the writer localizes the news story and gives it expanded meaning.

Military news, such as changes in regulations, pay, mission or anything affecting military readers, could also interest general readers. The alert and skillful writer can turn these bare facts, and sometimes dull items, into meaningful articles.

Writing About People

The typical military editor of a commercial daily often feels "handouts" (standard news releases) are hounding him to death. They choke his style. They keep him tied to a computer doing rewrites. He would

rather be working on a feature angle or out working up an enterprising story. He greets the daily handout pile as the worst part of his job. Why? Not because handouts do not contain legitimate news. Most of them do—buried somewhere behind, in or among fancy, \$10 words and reams of promotions.

Reporters say the typical military handout fails most often by the absence of names and addresses of those persons around which the story, event or action is built. They say infractions of several other basic rules of journalism also frequently draw the handout to the wastepaper basket, rather than to the printed page.

However complex and amazing a ship may be, a story that is more iron rather than flesh-and-blood often sails right into the wastebasket along with the larger part of the handouts of the day.

What most media want in the way of a Navy feature is a particular individual—Seaman John B. Boatwright, 20, of 2810 Prairie St., Landlock City—performing his duties to make the vessel an efficient ship. Names, properly spelled and accompanied by ages and addresses, keep wire services and newspapers in business. Details of ships or stations are interesting to people back home, especially if those facts relate to sons, daughters, husbands or hometown acquaintances. A sparkling story about a search and rescue, for example, is a natural, both from hard news and feature standpoints—if those indispensable names, ages and addresses are included.

STRUCTURE

The basic structure of the feature story is divided into three parts: the lead, the body and the conclusion.

Lead

Any standard news or magazine-style lead may be used to begin a feature story. It should, however, always be written in a manner appropriate to the subject. A light, humorous lead, for example, has no place at the beginning of a serious article designed to provoke deep and serious thought in the reader. On the other hand, a ponderous lead is no way to begin a light or humorous piece.

A simple summary lead was used to begin the following story:

A six-month renovating job on a dilapidated 70-year-old house won praise from a local real

estate board for a U.S. Navy captain stationed here.

The preceding lead is adequate as a starter, but another writer used a question lead. The question lead is often used for good effect in feature story writing. Leads like these, when well-phrased, send the reader along into the body in quest of an answer to such a “way-out” question:

Ever hear of a “hurevac”?

It is a hurricane hideout. The 8,000 acres that constitute the Naval Auxiliary Air Station Meridian, Miss., are a rolling woodland, and it would seem they would be unaffected by the hurricane season hundreds of miles away from Florida. Such, however, is not the case.

Note that in feature writing, the lead often consists of more than a single paragraph. Sometimes the lead runs for several paragraphs. Take the following feature lead for example:

Fifteen months ago, a young Greek Cypriot landed in New York city and took a job in a Brooklyn factory devoted to the manufacture of electrical appliances.

When he arrived, he could speak only a few words of English and that with thick accent.

Today that young man is Fireman Andreas Kalivakis, serving as an electrician aboard a U.S. Navy warship. His accent is fast disappearing; his English vocabulary is excellent and he is the owner of a new certificate indicating he has passed all the tests required to prove he has the equivalent of a U.S. high school diploma.

That lead stands the test for feature story leads; it grasps the reader’s interest immediately and makes the reader want to read more. A Marine Corps release excited the curiosity of the casual reader with the following lead, then added a startling transition that prepared the reader to take pleasure in completing the story:

Okinawa is far from the green hills of the United States, but an old-fashioned American-style still is in daily operation there alongside the radio section of Headquarters Company, Ninth Marine Regiment, Third Marine Division.

The still, however, doesn't produce alcoholic beverages—it produces pure, distilled water.

Often a lazy journalist—relying on the belief that Sailors are naturally interested in articles concerning their food, pay and equipment—will hang a dull lead on stories about those subjects. However, professional writers will give their best efforts to those stories, because they know these stories will be read by the greatest number of people and be of service to them.

A dramatic example of wide interest to food comes from the guided-missile destroyer USS *Semmes*. Annual competition for the Ney Award for the best mess afloat sparked an enterprising skipper to support wider dissemination of his ship's cooking secrets. *Semmes* published a cookbook of Navy recipes, cut to manageable portions, and the whole country took note.

Food editors featured the story in papers in New York, Chicago, Philadelphia, Pittsburgh, Indianapolis, St. Louis and Boston, as well as Charleston, SC., Dayton, Ohio, Evansville, Ind. and Norfolk and Portsmouth, Va. Also, numerous network and local radio/television stations made wide use of the feature material.

Veronica Volpe of the Pittsburgh *Press* wrote the following example:

For those unaware of the military usage of the word, the phrase 'the best small mess in the Navy' might have questionable connotation, least of all merit. Not so to the crew members of the USS *Semmes* just returned from a Mediterranean tour and now undergoing overhaul in Norfolk, Va.

The military usage of "mess" relates to its original meaning—that of a group of persons who eat their meals together, as do the men of a ship's company or an Army group. ...

An important fact to keep in mind when writing about Navy equipment and weapons is that the reader can soon lose interest in a dull story about a machine or weapon. What the reader is interested in is the men and women in uniform who will handle, install, maintain and operate those inanimate—and intrinsically dull—pieces of hardware.

The effect of the machine on the person, and the person on the machine, must be presented in a way that emphasizes people, and the writer must make those people into rounded characters who become real in the reader's mind. In other words, the story must have human interest.

The writer of the following feature lead did just that by beginning a story in the following way:

The machine, a metal monstrosity, squatted in the center of the metal deck, circled by a knot of Navy men: a bemused young officer, three puzzled Sailors and a knowing old chief.

"I know what it's supposed to do," the first Sailor said, "and I know where we're supposed to bolt it down, but who's ever going to operate a Rube Goldberg puzzle like that?"

"You are, buster," the old chief said, "and ...

Body

When you write the body of a feature story, it is important for you to avoid monotony. You do this by varying sentence length, however, long sentences must be clear and easy to understand.

Note the varied sentence length in the following feature from the Indianapolis *News*:

The first—and last—issues of eight newspapers were published at Ft. Benjamin Harrison the other day.

But their brief life span had little relationship to the energy and interest devoted to their publication. The papers were the last journalism exercises for 70 servicemen and women, graduating with a newspaper in one hand, and a diploma from the Defense Information School at Ft. Harrison in the other.

From all the armed forces, staffers in the "quill and scroll" exercise got a glimpse into their military future. These military journalists will go to assignments throughout the world. Many will find jobs on more permanent newspaper staffs, using what they learned at Ft. Harrison.

Nine weeks ago, this basic military journalist class began. Since then students have spent 209 classroom hours in the Basic Journalism Department. ...

Another point to note is the use of quoted material to carry the story along. Skillfully conducted interviews with articulate experts will provide the writer with quotations. Such quotations, interspersed with expository material, help move a story along and maintain a lively spark throughout. Explanations and readily comprehensible revelations from authorities in a given field impart an air of authenticity to writing,

particularly in stories about technical subjects, such as rocketry, instruments, engine improvements, jet engine overhaul and nuclear propulsion.

However he or she chooses to explain technical subjects, the writer should always remember the need to translate technical terms into lay language for the sake of the general audience. When this is not possible, the writer must define the technical terms.

When you write a feature on a technical subject, use the following points to help you plan and organize the body of your material:

- Make paragraph beginnings forceful to impel the reader through the story.
- Use technical terms sparingly, and include informal definitions as you go along.
- Dress up difficult or dull passages with human interest items.
- Quote authorities as necessary to make the reader feel the facts are authentic.
- Simplify facts by the use of analogy.
- Break down statistical material into figures the reader can comprehend.
- Compare scientific concepts and technology to objects with which the reader is familiar.
- Weave the necessary background into the story for unity and coherence.

For example, assume you are describing some microtubing used in a new guided missile. If you tell the readers it is three one-thousandths of an inch in diameter, they will have trouble visualizing it. Tell them it compares in size to a human hair and they can visualize its size immediately.

In another story, you can point out that a new jet aircraft carries more than 17,000 gallons of fuel. This is an impressive figure, but it does not mean much to the average reader. It would be more meaningful for you to tell the reader that the same amount of gasoline could power his car for the next 20 years.

Whenever possible, avoid generalizations. Use figures to back up any broad claims you may make. Do not merely say that the average Sailor uses too much water aboard ship. Add force and emphasis to the statement with understandable figures. Tell the reader the average Sailor drinks from two to four quarts of water a day. He uses five gallons of water daily merely to shave, brush his teeth and wash his hands. Cleaning

and food preparation in the galley takes an additional five to eight gallons per crew member. In addition, he uses up to 10 gallons of water when he takes a shower. Then tell the reader why this is important: because the Navy “makes” its own water, drop by drop, by distilling it from seawater.

If pictures are not available and you have to describe a mechanical device, describe it in terms with which the reader is familiar: “The Navy’s new supercavitating propeller looks like the screw part of an ordinary kitchen food grinder.”

In studying feature techniques, the writer should not overlook the finest training material of all—the published work of other feature writers. When you discover a piece in a newspaper or magazine that particularly interests you, you should read it again and analyze the devices the author used to make the work interesting, informative, entertaining or gripping. With a little adaptation and practice, you can make the same techniques your own.

One thing you will probably discover is that when a story leaves you with a satisfying aftertaste, it is often because it was good enough to hold your interest to the end—and because the ending was a piece of artistic writing in itself.

Conclusion

The conclusion of all good feature stories terminates the article in a positive manner. As in the lead, the writer is limited only by the ability in composing a conclusion.

One device frequently used is to summarize the key points of the story. Another way to end a story is to present a new fact, generally a fact that highlights the importance of the subject of the article. No matter how you do it, though, the ending should leave the reader satisfied that the time spent reading the piece was time well-spent. If you provided a tantalizing lead and a well-constructed body that held the reader’s interest, you owe to the story and the reader an equally well-written conclusion.

As mentioned earlier in this chapter, the feature lead example about USS *Norfolk* intercepting the Russian missile-loaded freighter sums up the action and puts the story in a new light by using a different twist. Consider the following excerpt:

Eventually, on orders from Moscow, canvas was rolled back on all eight 70-foot missiles. In six hours, governments had been contacted,

orders issued and received, proving photographs taken, and not a shot was fired.

Suddenly the meeting was news—as much so as if it had been a major naval engagement—but not a shot was fired. The dull patrol of USS *Norfolk* had been broken, and momentarily the endless watches became meaningful. Its mission had been accomplished.

The next day, *Norfolk* returned to its station on the now familiar patrol and observed a famous armistice on Veterans Day, November 1962, itself the new veteran maintaining the armistice in a new kind of war.

Not a shot had been fired. The “war” in Cuba was still cold.

A choice quote from an interview often makes a good ending for a feature story. The following example is how a Navy Journalist concluded a story about a group of circuit-riding Navy dentists and technicians conducting a people-to-people dental program in Africa:

“We’re glad to get out with the African people,” said Nicholl (a chief Dental Technician). “The fact that there’s an element of danger in it is overshadowed by the thanks of the people we’re helping. We’ve never left a village or hamlet without a barrage of cheering and clapping from our patients.”

The story on the new piece of machinery ended with the following paragraphs:

Sure, they had hated it to begin with, that monstrous machine, but now it was their monstrous machine. Constant association and the care they had lavished on it had made it their baby. The ugly monster had become an object of beauty to them, a delicate thing to be protected.

A passing Navy Journalist, new on board, stopped to drink in its loveliness. He looked as though he might be going to touch her. “Keep your cotton-pickin’ hands off the baby,” Quinlon snarled, and the other two baby-tenders curled their lips at the JO until he scuttled away. ...

PERSONALITY FEATURE

Personality feature is similar to other features in that it appeals to people’s interest in other people. It

normally points out special achievement, success or obstacles surmounted in life and centers on a particular event or achievement.

The manner in which personality features differ from other features is that they are almost always about a single individual. This type of feature gives interesting information about the person’s life, rather than just the person’s opinions. The properly written personality feature is a vivid word picture of the subject’s personality traits and physical features as well as a description of the things that make the person unusual or interesting. The effective personality feature leaves readers feeling they have met the subject face-to-face and know that individual personally (see figure 3-3).

Research

Since the personality feature story delves so deeply into the subject’s traits and physical features, considerable research is required. Most of the required information must be gathered through interviews. Conduct interviews with the subject and persons who intimately know the subject or have something to contribute. Some information can also be obtained from printed background material and from personal observations of friends and associates of the subject.

Personality features should contain the following information:

- Biographical data. Use only that biographical data you feel is necessary to your story (i.e., age, hometown, parent’s names, major duty assignments, time-in-service, marital status, etc.). Unimportant statistics and data tend to bog a story down and make for dry reading. The tone of a story usually dictates the amount of data required.
- Description. Describe the person, the details of the setting, surroundings and general atmosphere.
- Quotes. Use quotations from the interviewee in which that individual’s principles for attaining success, and so forth, are related.
- General accounting. Present a general sketch of personal achievement, success and so forth, in the words of the interviewee or friends of that person.

Presentation of Information

In addition to the feature writing methods mentioned earlier in this chapter, personality features require a few techniques all their own. There are methods that can be used to enable you, as the writer, to make your readers feel they have met your subject face to face, heard that person speak, seen the individual act and know the thoughts or opinions and past life of the person. These methods are discussed in the following text:

- Telling of characteristic mannerisms and actions
- Using direct quotations in a characteristic manner
- Actually describing the subject's personal appearance, demeanor, facial expressions and dress in his or her environment (fig. 3-3)
- Giving the opinions of others about the subject
- Showing how friends and associates react to the subject

The following personality feature excerpts should help you see how some of the techniques are used:

Bryan Tyler of the station's imaging facility approaches his art seriously—with strong conviction and knowledge developed by extensive formal training and much practice.

He does not like photo contests although he has won many of them. He would rather focus

Figure 3-3 Personality feature photo.
(Photo by JOCS (AW) Jon Gagne)

on the effects of people rather than photograph people themselves—but does both well. ...

Tyler is a sensitive artist who knows how to take, and more important, why he takes photographs. ...

"I like taking peopleless photographs that relate directly to man either by content or implication," Tyler puts it.

During a tour of duty in Washington DC., the lanky Virginian worked primarily with official portraits.

"It can be frustrating shooting portraits," emphasizes Tyler as he strokes his bushy black hair. "Everyone dressed the same with his only identity worn on his sleeve and placed in the same sterile environment. The portraits I keep, and feel satisfied with, show people in their own environment, or in a meaningful situation, hopefully conveying some insight into the subject."

"In Petty Officer Tyler, I think we have one of the Navy's finest," said his commanding officer, Capt Rose Grosbeak. "There's not one person here who doesn't feel that way about Bryan."

Tyler finds stimulation and excitement in searching for and producing meaningful photographs, even in the most mundane jobs. ...

"Photography should never end," Tyler reflects. "All you should do is change subjects and fulfill some meaningful purpose, either to me or to the person for whom I am shooting."

The material presented here gives the beginning feature writer a start in the right direction. Writing courses, taken from time to time, can help. Criticism from experienced feature writers and editors is a great aid. Studying the work of other writers, as mentioned earlier, is a fine guide to improvement. Reading about writing alone, however, never taught anyone to write. Like the disciplines of newswriting, the art of feature writing is learned by doing—**by writing**.

THE SPEECH STORY

LEARNING OBJECTIVE: *Recognize the fundamentals of writing a speech story.*

Figure 3-4.—A speech story features something not officially disclosed before.

(Photo by R. D. Ward)

Often, Navy JOs become jittery when first assigned to cover a speech story because they do not think they can get the facts or put them into story form. Actually, any writer who knows the fundamentals of news reporting can write a speech story.

First, the writing of a speech story resembles any other news story in many aspects. The most important fact, the climax of the story, goes in the lead. This usually means that the most important thing the speaker said goes in the lead. Occasionally, the most important fact may be something unusual—audience reaction, for instance—but generally, what the speaker said, either in quote or summary, is the feature.

The Secretary of Defense (SECDEF) may cover four major topics during an address, but the main point may have been the disclosure of a pay increase for all military personnel. This fact goes into the lead as depicted in the following text:

“All active-duty military personnel will get a four percent pay increase January 1,” said Defense Secretary Justin N. Case in a speech before the National Press Club last night.

Merely that a speaker appeared before an audience has very little story merit. The speaker must say something newsworthy—something that has not been officially disclosed before. This normally happens when a speaker appears before the media in a news conference (fig. 3-4).

The subject title of the speech is rarely important enough to become part of the lead. Speech titles are usually catch phrases that reveal very little about what is the most important part of the story. For example, when the President of the United States speaks, the lead features what he said in the following manner:

“The president, in a major speech tonight, called for another tax cut. ...”

If the writer started off with the information that the president spoke, no one would have much insight into the importance of the speech.

In structuring the speech story lead, include **what** was said and **who** said it. **When** and **where** it was said can usually be included within the lead, if the lead does not become too cumbersome. If it does, include them in the second paragraph.

Usually a direct quote lead will not do, for most speakers do not summarize their talk in one sentence. Thus the writer should paraphrase the lead, summarizing what the speaker said in one brief sentence.

PARAPHRASING

When you paraphrase, you must be careful to keep the speaker’s meaning. Do not quote out of context; that is, do not quote a sentence that gives a wrong impression when used alone.

For example, a reporter hears the president say, “I haven’t decided to seek reelection. However, I have instructed my staff not to be too hasty in looking for new employment.” If the journalist had quoted that first sentence alone, he would have given the impression that the president was not planning to run for another term in office, when that obviously was not what the president meant.

QUOTES

When quoting, wait for a striking phrase or summary of a key point. Use quotes in a speech story to give the flavor of the speaker’s talk. With quotes you can convey to the reader what the talk was like. To do this, the writer need not quote whole paragraphs because they make the copy dull. A few good quotes scattered throughout the story are enough.

To use quotes, you must understand the basics of quoting. A quotation must consist of the speaker’s exact words. The writer should not change one word. You must use quotation marks at the beginning and end of the quote as in the next example: “I think, therefore, I am.” You must use a comma to set off the quoted part of the following sentence: He said, “That did it.” To add the words “he said” at the end of the sentence, put the comma after the quoted matter and before the quote marks: “That did it,” he said.

When quoted matter does not make a sentence, use no comma and no capital letter to introduce the quote as in the following example: He did not “purge them.” Note the periods and commas are always inside the quotation marks. No comma is needed after a quote if it asks a question such as in the following: “Did you go?” he asked. Also, no comma is needed with a quoted exclamation point as in the next example: “What a view!” yelled the astronaut.

On occasion, a speaker may make an error he does not acknowledge during a speech or news conference. If you must use this particular quoted material, insert **[sic]** immediately after the error. This shows, for the record, that the speaker made the error and not the writer. Consider the following example:

“NASA has experienced a very good safety record since the Challenger disaster in early January [sic] 1986. During this time frame ...

Handling Long Quotes

Consecutive paragraphs of quotations do not require quotation marks at the end of each paragraph. These are required only when the entire quote ends. You do, however, begin each new paragraph with quotes. Nevertheless, as stated earlier, you can write more effectively by not using long quotes.

The ellipsis is a device of punctuation used in quoting. It consists of three spaced periods (...) used to show omission of a word or words necessary to complete a statement or quotation. If a quote is long and a writer wants to use it, the writer can delete the unnecessary words by using the ellipsis. However, too many beginners go wild with the ellipsis. They overuse it, sticking the three dots in every sentence. If you must use several ellipses to convey the message, it is better that you paraphrase the sentence.

If the writer starts a quote in the middle of a speaker’s sentence, the ellipsis need not be used before the quoted words. For example, the speaker may have said the following: “Considering all factors, and my staff has done that for many months, I feel the trainee would be ready for duty in a combat zone after 20 weeks of basic training instead of the present eight.” A JO’s sentence may read like the following: General Needam said, “The trainee would be ready for duty in a combat zone after 20 weeks of basic training instead of the present eight.”

Then, if you want to end a quote in the middle of the speaker’s sentence, leave four dots—three for the

ellipsis and one for the regular period as follows: “The trainee would be ready for duty in a combat zone after 20 weeks of basic training. ...”

Quoting is only a part of writing the speech story. The writer must still identify the speaker no later than the second paragraph. Many times the speaker will be identified in the lead.

Even when you think a person is well-known, you must still include a full name and full title in the story. That way the reader will know exactly who you are quoting and will not confuse that person with someone else with the same name or similar position.

If someone is relatively unknown, you may use a general job title for the first identification, such as a college president or a city administrator. Include the speaker’s name in the second paragraph.

Quote-Summary Method

Combining the guidelines concerning quotes and the material covered earlier about identification, a lead and the second paragraph for a typical speech story should read in the following way:

President Roland Coaster has asked the Defense Department to revise its training and education systems so every man and woman in the military service will come out with a skill marketable in the civilian economy.

In his annual manpower report to Congress, the president said, “There are some military specialists whose training does not lead directly to civilian employment. To help them, I have asked the Secretary of Defense to make available, to the maximum extent possible, in-service training and educational opportunities that will increase their chances for employment in civilian life.”

An example of a lead with a lesser-known person may read as follows:

The Navy’s Chief of Information said in a speech last night that his office was requesting more than 100 additional public affairs duties and emphasized that a preplanned public affairs program was essential.

In the second paragraph the writer usually gives a fuller identification of the speaker, the occasion of the speech, where it was given, and, if there is room and it is noteworthy, the attendance. Next, the writer uses the **quote-summary** method of organization.

The quote-summary method uses one paragraph of quotes from the speaker, then one of the writer's paraphrase. It does not matter which comes first—quote or summary. This method allows the reader to get the flavor of the speech through the quotes and enables the writer to reduce the length of his story by summarizing large portions.

For example, the following is a quoted paragraph followed by a paraphrased paragraph:

“Our children can read, write, spell, do arithmetic and use grammar, which is more important than learning a lot of meaningless rules.”

In criticizing drill, or rote teaching, the school superintendent argued that under former methods a child might win a medal in American history and still not understand the meaning of American democracy.

Notice that the paragraph of summary is related to the quoted one. The speech story, like any other, keeps

related material together. Table 3-1 illustrates a speech story using the quote-summary method.

ATTRIBUTION

Besides the organization of the story, the JO must be aware of other problems in the speech story.

Attribution—identifying the source of information or opinion—is needed in almost every paragraph. The writer must make it clear who is talking. Thus the writer should include attribution often. Beginners should attribute every sentence expressing opinion, for too often the reader forgets, and it seems the writer is making the statements in the story.

Attribution may consist merely of the phrase “he said.” However, to be sure the reader does not forget who the speaker is, the writer should occasionally insert the speaker's name. The writer may put the attribution at the beginning, middle or end of the sentence, but the natural place for attribution is at the end of the sentence.

Table 3-1.—Speech Story Using the Quote-Summary Method

Quote	“Take care of your men and women. They are the Navy’s most precious resources.”
Summary	This was the keynote of a speech delivered Friday by Radm. Helen O. Troy, Assistant Chief of Naval Personnel for Education and Training. Speaking before the class of the Naval Officer Candidate School here, Radm. Troy emphasized the importance of maintaining good relations between officers and enlisted personnel.
Quote	“The Navy into which you are now going for your first assignment has a number of problems facing it,” Radm. Troy said. “One of the most serious is the failure of a high percentage of our first cruise Navy men and women to reenlist.”
Summary	Citing current facts and figures, the admiral pointed out that the reenlistment rate among first-termers was low. It would have to be doubled if the Navy hoped to meet its manning requirements 10 years from now.
Quote	“You must know your men and women and take care of them,” the admiral continued. “These are the cardinal rules. But I add two more: know what they are supposed to know, and help them learn it.”
Summary	Radm Troy advised the graduating officers to study the same training manuals the enlisted community studies for advancement. She told them to use the same terms and the same approaches to their work that are taught to enlisteds in their schools and in their textbooks.

When writing a speech story, never use such words, unless quoted, as “I,” “our,” “us,” “we,” “me,” “you” or “your.” Standing alone, these words represent the writer’s viewpoint. So, if the speaker says our country needs more nuclear surface ships, the writer says: “The United States needs more nuclear surface ships.” If the speaker says “I,” it means just that and not the newswriter.

“SAID” AND OTHER VERBS

Many reporters covering speeches are tempted to use vivid words to describe how the speaker talked. Unfortunately, the truth often conflicts with the vivid verbs. The best verb to use is “said.” Here is the natural and neutral link between the speaker and what he said. But many writers feel their creativity is stifled by using too many “saids.” There are, of course, synonyms like “cajoled,” “pleaded,” “beseeched,” “asked,” “murmured,” “digressed,” “asserted,” “told,” “declared” and thousands of others that can often be used for variety.

When using these words to describe how the speaker expressed himself, be sure you describe the speaker’s emotions accurately. Always be alert to exact meaning and connotation.

PAINTING A PICTURE

To add more color to the story, the writer may occasionally describe interesting hand movements or gestures the speaker made. An example appeared earlier in this chapter when Petty Officer Tyler emphasized a point as he stroked his “bushy black hair.”

When former Russian Premier Khrushchev removed his shoe and pounded it on a table at the United Nations, every story covering his speech included it high in the account. Most speakers will not be that flamboyant, but they may raise a hand toward the ceiling or pound on the lectern for emphasis. An occasional mention of this adds flavor to the story and points up what the speaker feels is important.

GETTING THE FACTS

Before writing the speech story, you must get the facts. Most reporters depend on tape recordings or a copy of the speech. Frequently, a speaker may be approached—either directly or through his public affairs staff—for a copy of the speech if it is not supplied in advance.

Should you find yourself in a situation where you must rely on your own note-taking to gather facts, make sure you get the main points of the speech. A JO is not expected to be a stenographer, but you will still be held accountable for what you write. So listen carefully and write those quotes accurately.

Most professional reporters have their own system of note-taking, which usually consists of shortcuts. For example, a writer may drop all vowels from words—Sailor becomes “slr,” soldier becomes “sldr,” and so on. Similarly, the reporter may not dot the “i’s” and cross the “t’s” when writing rapidly. If you want to write down the word *responsibility*, you might dash off “**respons**” and later, when looking over the notes, the scribbling will be understood. Use your notes while they are fresh in your mind.

By using a homemade version shorthand, you can listen to the meaning of the speech. You are waiting for the important points of the speech, not mechanically copying down every word as a stenographer does.

In summary, remember the following key ideas about speech stories:

- The most important fact goes in the lead (what and who said it).
- Use ellipses to handle long quotations.
- Use the quote-summary method to organize the story.
- Learn to attribute information or opinion in the story.
- Use vivid words carefully.
- Get the facts straight. (Use your notes, tape recorder and a copy of the speech when possible.)

THE SPORTS STORY

LEARNING OBJECTIVE: *Recognize the principle of sports writing, the structure of a sports story, the use of quotes, the various sports writing rules and considerations and the sources of sports information.*

Sportswriting, whether it is for a great metropolitan daily or for a four-page internal Navy publication, can be the very lifeblood of a publication. No other editorial phase of a newspaper has quite so much to offer the writer—or so much to challenge the writer’s imagination and creativity (fig. 3-5).

Figure 3-5.—Football is one of a wide array of Navy sports the Navy Journalist will cover.
(Photo by PH1 (NAC) Mark Kettenhotten)

Sportswriting is a difficult side of journalism. It is tricky for the sportswriter who regularly covers a National Football League team. It is tricky for the JOSN who wades through the task of writing an eight-inch story about a touch football game played on the base yesterday.

For some people, sportswriting is easier than for others, probably because they are athletes or because they are longtime fans. It is not true, however, that only ex-jocks and channel-hopping sports addicts can write sports. With a little training and practice, any writer can become, at the very least, an adequate sportswriter.

SPORTS WRITING STRUCTURE

Writing about a game or a sporting event is essentially the same as writing a straight news story. Like straight news, sports stories are written in the inverted pyramid style (discussed in the previous chapter). The main difference between sports and news writing is in the lead. A sports lead usually emphasizes the **who** and **how** of an event, while a straight news lead usually emphasizes the **who** and **what**.

Like a news story, the lead is normally a one-sentence summary of the essential Ws and H, the bridge links the lead to the body, and the body is written to present facts in descending order of importance.

We will now examine the lead, bridge and body of sports stories in more detail.

Lead

Sports leads normally use the who and how as the lead emphasis. Leads should include the **who**, **what**, **when**, **where** and **how**. The **who** may be the teams

involved or the names of key players. The **what** will normally be the name of the sport, league or tournament. The **when** should be the date or day of the event, and the **where** should be the location of the event. The **how** is usually a brief description of how the game or contest was won and the score.

SUMMARY LEAD.—In a summary lead, the **who** and **how** will be the lead emphasis. The final score should be in the lead and **not** repeated elsewhere in the story. Many beginning writers, in an attempt to summarize the game, repeat the score in the body. This is wrong. If the reader forgets the score, he can easily refer to the lead.

Consider the following example:

Alvin Gecko's second-half scoring binge led the Pensacola Goshawks to a come-from-behind 94-93 victory over the Saufley Mole Chickens in Wednesday night's basketball opener at Tallship Field House.

In this example, the lead emphasis is Alvin Gecko (who) and his scoring binge (how). This is a classic who and how summary lead, highlighting the key player and how the game was won. This is the tried-and-true sports lead, and the type all sportswriters should master.

BACKGROUND INFORMATION LEAD.—The background information lead is another type of lead you should know about. It is a lead many sportswriters now use, especially when writing about games that have been broadcast over radio or television. Since readers are likely to know in advance the final score, who won and how the game was won, many sportswriters write leads that emphasize background information or locker room quotes to attract the reader.

The following is an example:

If Myra Naviete's sprained ankle slowed her down Saturday night, you couldn't prove it to the Naval Station Miami Pirates.

The speedy forward, who was sidelined three games because of an injury, scored 23 points to lead the Naval Security Group Hialeah Seminoles to a 56-37 victory over the Pirates in women's basketball action at Milander Gym.

Or:

Ugly.

That's the word coach Thomas Katt used to describe his Century Dolphins' 88-79

basketball victory over Rainbow Central here Friday night.

(Bridge) “We stunk up the gym,” Katt said. “I hate to say it,” he added, “but the better team lost tonight.”

Note that these leads emphasize background information and are not one-sentence summary leads. They still include the essential Ws and H. Some newer journalism textbooks advise sportswriters to write this type of lead and to stay away from the simple summary lead. You may wish to follow this advice as you develop your sportswriting skills, but first you should master the bread-and-butter summary lead.

Bridge

Bridges in sports stories serve the same purpose as news story bridges, primarily to link the lead to the body. Like news story bridges, they are often categorized by the purposes they serve, easily remembered with the acronym **WAITS**:

- W—Ws or H not answered in the lead are answered in the bridge.
- A—Attributes information found in the lead.
- I—Identifies persons or groups impersonally identified in the lead.
- T—Ties the story back to a previous story.
- S—Secondary facts are brought out in the bridge.

Very often, sports bridges are used to bring out secondary facts that explain the significance of the game. The bridge might, for example, explain that a loss drops the team into the losers’ bracket in a tournament, that a victory ties the team for the league lead, that a loss marks the fourth in a row for the team, or any other important consequence.

Consider the example that follows:

The shutout is the first suffered by the Fightin’ Giant Lampreys since losing 24-0 to the USS *Greystone* in the second game of the 1992 season—39 games ago.

Or:

The victory extends USS *Saufley*’s winning streak to eight and extends its lead to four games over the second-place Naval Hospital in the Blue and Gold Division.

Body

Many beginning sportswriters incorrectly write the bodies of their sports stories chronologically. However, if the key play took place in the fifth inning or the third quarter, that is where the body should begin. Usually, the key play will be one that breaks a tie or gives the winning team the go-ahead margin. In baseball, it might be a four-run inning; in football, it might be a 60-yard touchdown pass; and, in basketball, it might be two clutch free throws in the final seconds.

Sometimes, the key will be a defensive play. It might be a blocked punt or a diving catch in the outfield that prevents three runs from scoring. Sometimes, no single play will stand out. Then it is up to the writer to choose what to highlight. Analyzing statistics and interviewing coaches or players after the game can help you isolate turning points in the game.

If a key play happens to be an error, do not be afraid to write about it. Athletes put themselves in the public eye whenever they take the field, opening themselves to praise and criticism. If, however, you are writing about youth activities or a Little League game, it is appropriate to avoid mentioning the name of the player who committed the error. In such cases, attribute the error to the team or position.

It is not necessary to write about every inning, period or quarter of a contest. If nothing of consequence happened during a period or over several innings, you do not have to explain that nothing happened. Rather, you may briefly explain with an introductory phrase like, “After two scoreless innings ...” or “Neither team could move the ball until ...” Do not bog your story down with detailed accounts of each batter or each ball possession; focus on the key plays.

USE OF SPORTS QUOTES

Quotes are used in the same manner as in newswriting. If you have quotes from coaches or players, weave them into the story. Use them to introduce, support or explain your account.

For example:

“We knew that (Scott) Glengarry was going to beat the secondary sometime,” said Blue Knights head coach Marc Antonius. “It was just a matter of time. With his speed,

nobody is going to deny him for four quarters,” he added.

Beat the secondary he did. On a third-and-12, following a holding penalty, Glengarry raced down the right sideline, then slanted toward the middle. Quarterback Cocoa Butler hit him at the 20, and Price could have walked in from there.

Or:

The Battlin’ Lemmings switched to a 2-1-2 zone early in the third period, and Stevens scored only two field goals the rest of the way.

“Gordian was killing us in the low post,” explained Earwigs coach Kelly Pritchard. “When we went to the zone,” he added, “we were able to double-team him and clog up the middle.”

ATTRIBUTION

Unlike newswriting, sportswriting requires little attribution. About the only attribution needed is for quotes or paraphrases. If the writer witnesses a game or event, he can write about the action without attribution. If he writes the story from scorebooks, he need not attribute the information because it is a matter of record.

SUPERLATIVES AND COLORFUL VERBS

As an observer, the sportswriter may inject his opinions concerning the action he witnesses. He might describe a team’s defense as “sloppy.” He might describe a catch in the outfield as “miraculous” or a basketball player’s leaping ability as “gravity-defying.” In newswriting, this is considered editorializing; in sports, it is the observation of a qualified observer. Do not overdo it, however, and do not confuse this freedom with a license to break the rules of newswriting. Save the superlatives for when they are warranted and for when you are confident you know what you are talking about. When in doubt, play it safe.

Similarly, the sportswriter is free to use colorful verbs or adjectives to describe how one team “smashed” or “clawed” its way to victory. People who read the sports pages or listen to sports broadcasts are accustomed to such language and expect it.

Do not, however, get colorful verbs confused with clichés. If you write “smacked the apple,” you are

resorting to a cliché. If you write, “smacked the ball,” you are using a colorful verb.

It is all right to use sports jargon, such as “threw a bomb,” “lobbed an alley-oop,” “turned a 6-4-3 double play” or “busted a monster jam,” when writing game accounts.

SPORTS TERMINOLOGY CONSIDERATIONS

You must know the terminology and the rules of the sport you are writing about. If you are not familiar with the sport, it is wise for you to start reading the sports sections of as many newspapers as possible to see how experienced writers cover games.

Use the terminology for the sport you are writing about. If you are new to sportswriting and are not sure of the terminology, play it safe. It is better for you to say a batter “hit” the ball or a quarterback “threw” a pass than to wrongly use words like “slammed” or “launched.” You will lose your credibility fast if you write that a team “edged” another team, 104-57, or that a quarterback “fired a nine-yard bomb.”

Write in the active voice as much as possible. Do not write “was won,” “were victorious,” and so forth. Write, instead, “defeated,” “blanked,” “overwhelmed,” and so on.

TROUBLESOME WORDS

A couple of words common in sportswriting trouble grammarians and some sports editors. The words are “win” and “host.”

Technically, “win” should not be used as a noun, and “host” should not be used as a verb, although many respected sportswriters and editors now accept such usage. Check with your editor before you write something like, “The victory marked the seventh straight win for the Eagles” or “The Eagles host the Naval Station Cervantes Cavaliers Friday.”

A similar usage problem arises with team names and pronouns. It is wrong for you to say, “NAS Pensacola began their drive on the 30-yard line.” “NAS Pensacola” is singular and “their” is plural. You should write, “NAS Pensacola began its drive. ...” You should use “their,” however, when you refer to a team by its plural nickname—Battlin’ Lemmings, Blue Knights, Fightin’ Giant Lampreys, Dolphins and so forth.

RANKS, NAMES AND NICKNAMES

In military sportswriting, it is common practice not to use ranks. However, your CO or office SOP may require their use.

Similarly, middle initials and such designations as “Jr.” or “III” are not used in sportswriting.

Nicknames, however, are common and should be used. The usual style for first reference is as follows: first name/nickname in quotation marks/last name. Note the following examples: Elvis “Toast” Patterson or Evander “Real Deal” Holyfield. Sometimes the nickname comes before the first name, as in “Neon” Deion Sanders. On second reference, only the last name is used.

NAMES AND NUMBERS

Just as in newswriting, names and numbers should stand out as red flags while copy editing; each must be double-checked. The difference in sports is that there are likely to be a lot more of both names and numbers.

Double-check name spellings and make sure numbers are correct. Also, make sure numbers add up, both in the story and in box or line scores.

SIDELIGHTS

Do not confine your story to action that takes place on the field. Use sideline information that may interest the reader: the size of the crowd, injuries that might have affected the outcome of the game, weather conditions and so forth.

TYPES OF SPORTS TO COVER

Sports encompasses more than just the big four (baseball/softball, football and basketball). On military installations, there are a number of other sports and recreational activities that warrant coverage, including bowling, tennis, racquetball, squash, golf, darts, boxing, wrestling, gymnastics, running, youth sports and hunting and fishing.

STRINGERS

For you to have a variety of sports coverage in your newspaper, you may have to develop a stringer system. It is important you remember that stringers are seldom trained journalists. Therefore, it is usually necessary for you to provide them with some training and brief them on your newspaper style and deadlines. More information on using stringers may be found in

Handbook for Stringers in the Armed Forces (NAVMC 26-84) and in the *JO 1&C*.

SOURCES OF SPORTS INFORMATION

A problem for many beginning sportswriters is knowing where to gather the needed information. Consider the following sources and note that officials are omitted from the list because they are seldom, if ever, a source of information:

- Morale, Welfare and Recreation (MWR) for the ins and outs of recreation, intramural and youth programs, including rules, schedules and official scorebooks.
- Coaches and managers for details about team members, lineups and rosters, game plans, quotes and information about a contest, especially a contest you did not cover yourself.
- Team members for accounts of what happened in the game. Be cautious. Many losing teams tend to blame the loss on the officiating, whether they lost by one point or 30 points.
- Official scorers for game statistics and scorebooks. If you run a box score of the game, be sure your stats match those of the official scorer.
- Fans for color and sidelight information, where appropriate. Often used in sidebar stories, fan reactions can help tell the story of a team’s success or misfortune.

Officials are impartial and usually refuse to comment. If an official’s call is vital to the story, do not expect him to explain or justify it unless it is a matter of rule interpretation. **Never** ask an official about judgment calls (balls and strikes, close calls on the bases, whether a receiver was in or out of bounds when he caught a pass, whether a basketball player traveled, etc.). Officials are, however, legitimate subjects for personality and rules clinic features.

Additional sports coverage guidelines (including help on compiling statistics) may be found in the latest edition of *The Associated Press Stylebook and Libel Manual*.

THE ACCIDENT STORY

LEARNING OBJECTIVE: *Identify the structure of the accident story and the methods used to gather accident news.*

Five Sailors are killed when one falls asleep at the wheel of his car after a weekend liberty.

A young Navy ensign dies in a flaming plane crash when something goes wrong with his jet during a routine training hop.

A Marine accidentally shoots a buddy with a gun he did not think was loaded.

An airman crosses an aircraft flight line and walks into the blades of a spinning propeller.

A civilian painter plunges to his death from a three-story Navy building when the lines in a scaffold break.

An explosion at a base facility kills 15 people and injures 35 others.

A Navy dependent child dies in an ambulance after drinking something from the family's medicine cabinet.

Accidents and disasters such as these take hundreds of lives each year. In addition to destroying life and property, they cause untold pain, misery and suffering to the victim's friends and relatives.

Yet, despite the undesirability of this type of news from the Navy's viewpoint, covering and writing accident stories are a part of your job (fig. 3-6).

Figure 3-6.—The Navy Journalist will write about many types of accidents, such as this aerial view of the Sasa Valley, Guam, crash site of Korean Airlines flight 801.

(Photo by PH2 Rex Cordell)

The following is an important tenet of Navy public affairs: **Accident news cannot be avoided or withheld, and it must be released.** The amount of information released varies with security and next-of-kin considerations.

Accidents can happen anytime and anywhere. Because they are unpredictable, unfortunate and undesirable as a source of news, the JO who covers and writes accident stories must be especially careful in handling them.

Accidents involve both life and death. They may cause human suffering, heartache and anxiety. Also, because accidents sometimes result from carelessness or negligence, they may injure reputations or lead to disciplinary action. A careless word or phrase in an accident story may cause great damage to the Navy, to individuals involved and to the careless writer. Therefore, **accuracy is of utmost importance** in the accident story.

When collecting information for a story, the journalist must be careful to avoid gossip and conjecture. You must be able to seek out proper authorities and get your information right the first time. You may not have the opportunity to verify it later.

You must stick to the concrete facts, resist any temptation to hide or cover up legitimate news, maintain high standards of good taste and, above all, be familiar with security restrictions and other limitations. You must know what to release and what not to release. Never will your abilities as a JO be put to a more exacting test.

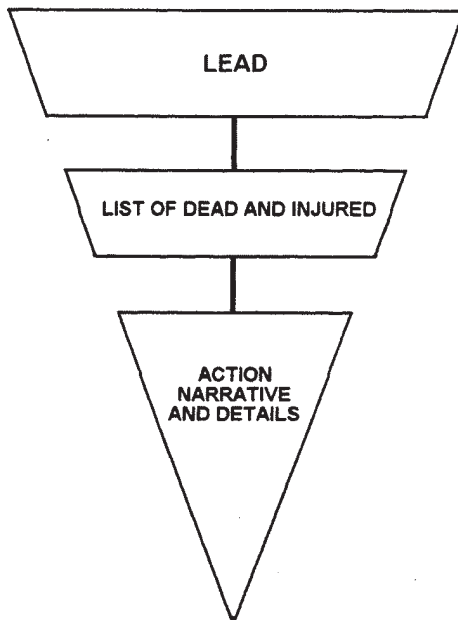

STRUCTURE

In any accident where a number of persons are killed or injured, the quickest and simplest way of writing the story is to use the accident/disaster story structure shown in table 3-2. This structure is adaptable to all types of accidents and enables you to get the most important facts into the beginning of the story.

Lead

The lead of an accident story introduces the reader to the basic facts in the situation by summarizing the five Ws and H (who, what, when, where, why and how). Consider this example: "Two San Diego Sailors were killed and three others seriously injured today

Table 3-2.—Accident/disaster story structure

when their automobile blew a tire and smashed into a tree on Highway 80, five miles east of El Cajon.”

Note that the lead answers all of the five Ws, but does not elaborate on any of them. The most important facts in any accident story are the number and identities of the casualties and the cause of the accident. This lead immediately satisfies the reader’s initial curiosity about these facts, but more detailed explanations are saved for the body of the story.

Since five persons are involved in this accident, it would not be practical to list their names and complete identities in the lead. Therefore, they are included in the next segment of the story.

Casualty List

The casualty list contains the names, ranks or ratings, ages, next of kin, hometown addresses and other pertinent information available on the dead and injured. A casualty list for the above lead might be presented in the proceeding manner (listing should be in alphabetical order to facilitate readers in scanning the list for known names):

Dead are:

Seaman Apprentice David K. Becker, 19, son of Mr. and Mrs. Daniel M. Becker of 821 Sherman Dr., St. Louis, Mo.

Seaman Jackson B. Painter, 22, son of Mr. and Mrs. Carl H. Painter of 680 Deamond St., Elmsdale, R.I., driver of the car.

Injured were:

Seaman Apprentice Bruce J. Burns, 22, son of Mr. and Mrs. Morgan J. Burns of Route 7, Nashville, Tenn., broken arms, shock.

Fireman Milton M. Jackson, 20, son of Mr. and Mrs. Ralph J. Jackson of 4210 Florida Ave., Lexington, Ky., skull fracture, internal injuries.

Engineman Third Class John C. Scole, 21, son of Mr. and Mrs. Alton H. Scole of 4109 American Ave., Long Beach, Calif., compound fractures, internal injuries.

The dead are always identified first in the casualty list, followed by the injured.

In identifying the victims, it is again emphasized that all pertinent information related to them be included in the list. A newspaper near San Diego might use only the victims’ names, ages and rates. The parents’ names and hometown addresses might be cut because they have no local news value.

The wire services, however, would want all the information. A story like this would be picked up and served to newspapers in the victims’ hometowns. Names of the parents and their addresses are important. By including all the information in your releases, you leave its use up to the discretion of the media. It may also save you the trouble of later answering queries for additional information. Also, note that the driver of the car has been identified among those killed and that specific injuries have been listed for those injured. Most newspapers follow this practice. This eliminates the need for cluttering up the body of the story with these details later.

If there are 10 or more casualties, the recommendation is that you place their names separately at the end of the story. The newspaper can treat the list as a sidebar or run the names in an adjoining box. Too many names in the casualty list cause a big break between the lead and the body, interfering with the story’s progress.

The use of a casualty structure has two distinct advantages for the newspaper. First, this treatment gives each name more prominence in the story because of the typographical arrangement. Each victim is listed separately. The reader does not have to ferret out their names from one long paragraph. The reader merely runs down the list quickly to see if there is anybody the reader knows.

Second, the casualty list allows for easier handling in both the editorial department and the composing room.

Let us say the previous story appeared in the first edition of a newspaper. By the time the fourth edition of the paper is ready to go to press, one of the more seriously injured victims dies.

If the casualty structure is used, a complete revision of the story is not necessary. The editor makes a few minor changes in the lead and body of the story, then moves the name from the “injured” heading up to the “dead” heading in the casualty list.

Casualty Releasing Policy

Under most circumstances, the names of casualties cannot be released until the next of kin have been notified. In this case, the story should be written and released in the customary manner. However, the space ordinarily reserved for the casualty list should include the following statement:

“Names of casualties are being withheld pending notification of next of kin.”

Later, when the names are released, a newspaper may insert them in the proper place in the story. However, it is neither necessary nor desirable to withhold the other facts in the story until the names are available.

Current policy regarding the release of the names of the dead and injured, such as what can or cannot be released, is contained in *Department of the Navy Public Affairs Policy and Regulations*, SECNAVINST 5720.44A. (This publication will subsequently be referred to by its short title, *PA Regs.*)

If only two or three people are the victims of an accident, their names and identities should be incorporated into the paragraph structure of the story. Do not list them separately, name by name, as in the casualty list.

Let us assume that only one person was killed and another was injured in the previously described auto accident. The following is the way the names would be handled following the lead:

Seaman Jackson B. Painter, 22, the driver of the car, was killed instantly. He was the son of Mr. and Mrs. Carl H. Painter of 680 Deamond St., Elmsdale, R.I.

Engineman Third Class John C. Scole, 21, a passenger, suffered compound fractures and internal injuries. He is the son of Mr. and Mrs. Alton H. Scole of 4109 American Ave., Long Beach, Calif.

BODY

The body of an accident story tells the complete story in detail. It may be developed in either logical or chronological order, but it should be written in a manner appropriate to the subject matter.

A straight fact story concerning a plane crash or an auto accident would ordinarily be developed in logical order after the casualties are listed. The most important facts would be presented first. An accident story, however, is most adaptable to chronological order development. In a heroic rescue, for example, where dramatic details play an important part, the story would be told in narrative form.

STYLE

The style for an accident story is the same as for all newswriting. Simplicity, clarity and brevity are essential elements. More than ever, the writer should tell the story and stick to the facts.

Maudlin sentimentality or emotionalism—the old “hearts and flowers” routine—must be avoided. Phrases such as “tragic loss,” “grief-stricken family” and “went to his final reward” are the marks of an amateur. They are banned in most newsrooms.

There are also certain errors in syntax that are peculiar to accident stories. Note the examples that follow:

- Death may occur following an operation or during an operation, but not as a **result of an operation**. This implies negligence on the part of the persons performing it.
- Accidents **happen** and explosions **occur**, but neither takes place. That would imply they had been scheduled.
- Everybody dies ultimately of heart failure, not of a heart ailment.
- A fire is not a conflagration until it sweeps a wide area. Conflagrations are rare. A fire approaches conflagration proportions only when three or four city blocks are aflame.
- A fire may damage, destroy, gut or raze a house. It does not, however, partially destroy it or burn it to the ground.
- Although commonly used, planes do not collide in midair. They may collide on the ground or in the air. There is no way of determining midair.

Weather often causes accidents and disasters that make news. In addition, gale warnings, storms at sea and hurricane evacuations play major roles in Navy stories. Simple weather terminology, however, is frequently misused by the Navy Journalist.

To avoid such misuse, some of the more common terms and their definitions with which you should become familiar are listed as follows:

- A **gale** is a strong wind with a velocity of 39 to 54 miles per hour.
- A **storm** manifests itself with winds of unusual force, ranging from 54 to 74 miles per hour. It is often accompanied by rain, snow, hail and violent outbursts of thunder and lightning.
- A **hurricane** or **typhoon** is a storm of intense severity and violence with winds exceeding 74 miles per hour. The difference between a hurricane and a typhoon is mostly a matter of geography. Storms west of the international date line are called typhoons; those east of the line are called hurricanes. Both are identified as cyclones in the Indian Ocean.

Certain medical terms crop up in accident stories from time to time. They should be simplified whenever possible as in the following examples:

- Abrasions—scratches
- Lacerations—cuts
- Contusions—bruises
- Trauma—shock

Damage figures are also frequently used. You should keep in mind that initial figures are usually estimates and should be stated as such. If the figures are unusual or high, they should be attributed to the authority who made them.

A person is widely known, not well-known. Nevertheless, even when widely known is used, it must be followed up with specific accomplishments.

Flowery euphemisms—once the rule in journalistic accounts of death—are no longer recommended in straight newswriting. They are less objective and are not acceptable to the reader. Why say remains, when body is a more accurate description? The body is placed in a coffin, not a casket. It is usually taken home, not shipped. Funeral services, not obsequies, are held. The body is buried, not interred.

The descriptive terms “young,” “middle-aged” and “elderly” are often misused because they are relative. The criteria used by The Associate Press is as follows: “A person is young until he is 35, middle-aged from 35 to 65 and elderly after 65.” But if you think a person’s age is important, why use descriptive adjectives at all? Why not merely identify the person as being 35, 52, 68 or whatever the age may be?

GATHERING THE FACTS

Gathering the facts for a routine Navy accident story is simple. Often, the best source of information is the personnel office. The “casualty report” made by the personnel office and transmitted by priority message will provide you with most of the necessary information (fig 3-7).

In gathering the facts for an accident story, make sure you get the following information:

- Casualty’s full name, including rank or rate, file or service number and branch of service.
- Status: Active duty or reserves.
- Type of death: Killed in action, died of wounds received in action or death from whatever cause; the extent of injury: Injuries sustained and medical listing of patient, when available. Remember to attribute the stated cause of death to competent authority when the cause is not perfectly obvious.
- Date, hour, place, circumstances and cause, when determined.
- Location and disposition of body.
- Full name, addresses and relationship of next of kin.

Figure 3-7.—Navy Journalists tell the Navy story.

(Photo by PH1 Jim Hampshire.)

- Information stating whether next of kin has been officially notified.

These facts usually provide enough information for a start. Note that the following report briefly answers all the questions necessary for an accident story. A few well-placed telephone calls will provide you with any other details you may need. The results may look something like those that follow:

Little Creek Sailor was killed today when his automobile went out of control, struck a railroad track and overturned on Sewell's Point Road near Ward's Corner.

The Sailor was identified as Gunner's Mate First Class John J. Doe, 37, husband of Mrs. Dolores E. Doe of 1717 Atlantic Ave., Atlantic City, NJ.

A veteran of 16 years naval service, Doe was attached to the Morale, Welfare and Recreation (MWR) Department, Little Creek Naval Amphibious Base. His death marks the first traffic fatality involving Little Creek naval personnel since February.

A routine accident story of this type usually runs about three or four paragraphs. It is brief and compact, yet contains enough information to satisfy the requirements of most newspapers.

All accident stories, however, are not this simple. When two or more casualties are involved, you will have to dig for more details and write a story with a casualty list. Listed next are some of the facts you should consider:

- Accurate number and complete identities of the dead and injured.
- Cause of the accident. Authoritative sources should be consulted and quoted whenever necessary. If the cause of the accident is not readily apparent, the story should state, "The cause of the accident is unknown and is under investigation." Although the exact cause of an accident may be unknown, qualifiers sometimes may be used to present a probable cause in the story. For example, "An eyewitness to the crash said that the plane struck a treetop during takeoff." The cause of an accident may be reported after a complete investigation has been made. Meanwhile, do not speculate in your release concerning its cause, especially when negligence or human error is suspected.

- Date board of inquiry will be convened and its members (if such a board is formed). Boards of inquiry usually are not formed unless the accident results in a major loss of Navy property, such as a shipboard fire. However, all aircraft accidents, even minor ones, are investigated thoroughly.
- Lives still imperiled. If people are still trapped, this rates coverage with the casualties and will require follow-up coverage as well.
- Property loss or damage. It is not necessary that you state the price of an airplane each time one crashes, but when a structure is damaged by the crash, media will want to know its value. You might want to keep a list on your desk of Navy aircraft and the approximate cost of each model.
- Disposition of the dead. State where the bodies have been taken.
- Care of the injured. Like the previous category, the care of the injured is especially applicable in off-station accidents. The story should state where the injured are being treated.
- Statements from survivors, especially where heroic acts are involved. Such statements are unnecessary in routine accidents. However, in a major catastrophe, they could be extremely valuable in piecing together a true picture of exactly what happened.
- Rescue work still underway. This is related to victims still imperiled.
- Human interest items. Noteworthy escapes, rescues or unusual circumstances involved should be acknowledged.

OTHER FACTORS TO KEEP IN MIND

Accidents are caused by various circumstances. The major causes for most accidents are human error, mechanical failure, disturbances of nature and "acts of God."

When a pilot misjudges the plane's altitude, attitude or airspeed and crashes upon the deck of an aircraft carrier, the accident is due to human error.

If a hydraulic catapult aboard the same carrier explodes and kills several Aviation Boatswain's Mates, the cause of the accident might be mechanical failure.

If the same ship were battered about in a violent storm at sea, and several crew members were injured when they were thrown out of their bunks, the accident could be blamed on disturbances of nature.

Finally, there are accidents that cannot be attributed to any of the above causes, and therefore, are classified under “acts of God.” Note the following example: A bee stings the coxswain of a motor launch, causing him to lose his footing, fall overboard and drown.

When an accident occurs in the Navy and an account of it gets into the newspaper, the reader automatically looks for someone or something to blame. The reader often forgets that circumstances as well as persons and things cause accidents.

In writing an accident story, the Navy Journalist should attempt to explain these circumstances. With proper handling, an accident story may result in a better understanding and appreciation by the public of the everyday hazards Navy personnel face.

Take, for example, an aircraft accident in which the pilot manages to parachute to safety just moments before his plane crashes into an isolated field. Regardless of the fact nobody was hurt and there was no private property damage, many readers will approach the facts with a negative point of view. Unless told differently, they will think about the story in terms of “carelessness” or “negligence.” Either the pilot did not know how to handle the plane, or the ground crew did not adequately prepare it for flight. These are typical reactions.

What the reader does not know, however, is that the plane might have suffered a flame-out over a heavily populated city. To protect the lives of people below, the pilot may have decided to stick with the disabled plane

until it reached an unpopulated area. In doing this, the pilot jeopardized his own chances for survival.

The reader never learns these facts unless they are mentioned in the story. Decisions and actions such as these should not be included just in the story; they should be featured in the lead. It is your responsibility to have the common sense and ability to recognize these facts and play them up accordingly.

In another story, a Sailor is killed in an auto accident. There is nothing unusual or spectacular about it. Nobody else is involved. The driver was killed when the car blew a tire on a sharp curve, veered out of control and smashed into a utility pole. Circumstances caused the accident.

Yet, when the story is published, a civilian reader may think—“Well, another one of those Sailors from the base killed himself today. I wish something would be done about their reckless driving habits. It is not safe to drive the highways anymore.”

In a story of this type, the circumstances should be carefully explained. It might also be pointed out in the story that this was the first auto accident in which a Sailor was involved in five or six months, if that is the case. Try to wrap up your story with some positive information.

It must be emphasized, however, that under no circumstances should facts be distorted or sugar-coated to put an accident in a favorable light. If mitigating circumstances exist, they should be reported. If they do not exist, tell the story straight and stick to the facts. You should strive to treat all stories as impartially and as objectively as possible. Never give a newspaper, or any other medium for that matter, less than your best effort.

CHAPTER 4

WRITING FOR MAGAZINES

The “Navy story” can take many forms. All must be considered, and each, depending on the nature of the material to be presented, should be used.

One of these forms is the magazine. Too often overlooked by Navy Journalists, this medium offers a ready market for virtually any subject one might consider. Since magazines cater to the tastes, temperaments, and interests of specific groups, they offer an excellent medium for you to reach exactly the audiences you desire.

These groups, with their special identified interests, provide a possible readership for many stories that have little or no appeal to the general public. An editor for the *Washington Post* would have extreme difficulty finding any news value in a story about a San Diego-based Sailor from Cleveland who collects coins. The editor of the *Numismatic News*, on the other hand, would welcome such an article and is even prepared to pay for it. The point is that the “Navy story” has many facets. Some are of interest to virtually everyone, some to relatively few. Whatever the case, all the stories should be told using the medium most appropriate for a particular story. Just remember—almost every story idea even one conceived with another medium in mind, is also right for some magazine.

This chapter acquaints you with the various types of magazines and magazine articles. It also introduces you to the composition and styles of magazine articles. Finally, it offers you some tips on researching magazines, researching story ideas, and getting your articles published.

MAJOR CLASSES OF MAGAZINES

LEARNING OBJECTIVE: *Recognize the major classes of magazines.*

In general, the four major classes of magazines are as follows:

- Consumer
- Trade, technical, professional and business
- Company (house organs)

- Service-oriented

CONSUMER MAGAZINES

Consumer magazines, the largest of the four classes, includes all those publications found on the newsstand (fig. 4-1). Their contents attempt to appeal to the general public or to large groups in our society that share common interests. With few exceptions, consumer magazines carry advertising and are sold individually or by subscription. A few magazines that qualify as “consumers” are sold only by subscription.

Consumer magazines are made-up of general interest publications and special interest publications. This distinction is made not so much for the readers as for the potential writers of magazine articles.

Magazines are purchased by people who expect certain things from a particular publication. For a magazine to be successful, those expectations must be met. Therefore, a writer must adapt to the style prescribed by a magazine’s editorial policy and submit only stories dealing with its expressed area of concern. Any disregard of this policy will result in a story’s automatic rejection, regardless of how interesting or well written it may be.

General Interest Publications

General interest publications, as the category implies, are intended for the general public. Their subject matter is broad, and their appeal usually transcends most of the boundaries of age, sex, race, education, occupation and geography. Magazines, such as *Reader’s Digest*, *Life*, *Parade* and *The Saturday Evening Post*, fall neatly into this category. Each contains a variety of articles to interest a diverse audience. Others, such as *Time* and *Newsweek*, also qualify as general interest publications. Although they concentrate primarily on news and current events, they still cover a wide range of subjects, offering something for everyone. Also, their material is presented in an easily read style that explains a news story in a way any reader can understand.

Some magazines originally published for specific groups now attract a wider audience because of

Figure 4-1.—Consumer magazines publications.

(Photo by JOCS (AW) Jon Gagné)

alterations to their contents or the changing interests of the reading public. *Family Circle*, for example, is not read exclusively by women, and men are not the only readers of *Gentlemen's Quarterly*.

Special Interest Publications

Special interest publications, as the term implies, are magazines directed at specific groups of readers with one or more common interests.

Some magazines attempt to cover all aspects of a broad subject, while others are concerned only with a particular element of the general subject. *Sports Illustrated*, for example, contains stories on practically any sport, but *Golf Digest* carries only stories related to golf.

Other special interest publications find their audiences through different demographic segmentations.

There are magazines published primarily for men (*Field and Stream*, *Men's Health*, *Gentlemen's*

Quarterly, and so on), and for women (*Cosmopolitan*, *Vogue*, *Woman's World* and so on), for boys (*Boys' Life*) and for girls (*Teen*).

There are magazines for various age groups. For example, *Senior World* is published for senior citizens; *Modern Maturity* for men and women 54 or older; *Mademoiselle* for college women, ages 18-22; *Careers* for boys and girls, ages 15 to 18; *Children's Digest* for boys and girls, ages 8 to 10; *Jack and Jill* for children, ages 6 to 8; and *Highlights for Children*, ages 2 to 12.

There are also magazines aimed at blacks and other minorities. *Ebony*, for example, is intended for black men and women and could be considered a "general interest publication." *Essence* is one of a number of magazines published with black women in mind, and *Players* caters to black male readers.

Some magazines are published for residents of a specific location, such as *Phoenix* for citizens of Phoenix, Arizona. Others, such as *Denver Living*, are for newcomers to an area. Still others, such as *Aloha*,

The Magazine of Hawaii, are directed toward potential visitors to a particular city, state or country.

There are magazines for the members of almost all religious sects (*Catholic Digest*, *Baptist Herald*, *Mennonite Brethren Herald*, *The National Jewish Monthly* and so forth) and most clubs, associations and fraternities.

In short, virtually every group has a corresponding consumer magazine published expressly for it.

TRADE, TECHNICAL, PROFESSIONAL AND BUSINESS

Magazines in the trade, technical, professional and business class are published for active business people. The readers of these publications are looking for ways to improve their businesses and increase profits. While they might appreciate a little humor in the articles and want the material to be well-written, they are not reading them for pleasure.

These business journals are designed to appeal to one of the following three specific groups:

- Retailers
- Manufacturers
- Professionals and industry experts

Retailers, along with business people who perform various services, are interested in such subjects as successful sales campaigns and unique merchandise displays. Manufacturers expect articles dealing with ways to solve industry problems, such as personnel absenteeism and equipment failure. Professionals and industry experts want stories about new techniques and technical developments in their respective fields.

All of these business people are interested in making money and managing their businesses more efficiently. Therefore, the primary purpose of each of the business journals is the goal of helping its readers do their jobs better. Besides stories about business trends and solutions to problems, these publications often offer advice on ways a particular business can be operated more profitably.

Trade Journals

While the term **trade journal** is often applied to all publications in the business journal class, there are subtle differences.

A trade refers to skilled work, usually requiring extensive training, but not necessarily formal

education, to master it. Carpentry is one example of a trade; printing is another. Therefore, a trade journal is a publication addressing the skilled laborers in a particular field, or the work they perform. *Motor Magazine* and *Ceramic Monthly* are examples of trade journals.

Technical Journals

Technical journals usually discuss sophisticated material, equipment or instruments and their use. Examples of technical journals are *Datamation*, *Broadcasting* and *Photomethods*.

Professional Journals

Professional journals are publications intended for professional people. This group primarily includes persons with a vocation or occupation requiring advanced education and training and involving intellectual skills. This group specifically comprises those working in such fields as law, medicine, theology, education, engineering, journalism and so forth. However, the term **professional** has, in general use, been expanded. It now includes the executives, managers, department heads, some staff members and even the sales force of most business enterprises.

Business Journals

There are business journals for those persons in, seemingly, every occupation imaginable. There is *Cashflow* for accountants, *Advertising Age* for ad agency personnel, *Chilton's Food Engineering* for those in the food and beverage processing industry and *American Psychologist* for psychologists.

There is *Scholastic Coach* for high school and college sports personnel, *Instructor Magazine* for elementary school teachers, *American Bee Journal* for amateur and professional beekeepers and *Grocery Distribution* for operators of food warehouses and distribution centers. *Police* is published for law enforcement personnel and *Editor and Publisher* for newspaper personnel. There is the *ABA Journal* for lawyers, *Private Practice* for medical doctors in private practice and *C&S (Casket and Sunnyside)* for funeral directors. *Across the Board* caters to business people.

COMPANY PUBLICATIONS (HOUSE ORGANS)

Unlike business journals, company publications, or house organs, are produced by or for the businesses or organizations they serve. Their readers need or want certain information about the companies for which they work, and the companies try to provide it.

There are six basic kinds of house organs. Many of the larger companies publish them all. A number of companies consolidate their news into fewer publications. Some small companies produce only occasional newsletters for their employees. Whatever the case, all have a need to communicate to an internal or external audience. And all have a need for material that will interest their readers.

The six types of company publications are as follows:

- Employee
- Customer
- Stockholder or corporate
- Sales
- Dealer
- Technical service

Employee

Employee magazines are designed to inspire and motivate employees. They keep workers up to date on company programs and policy and provide knowledge about employee benefits. They also provide recognition of the accomplishments of employees and inform co-workers of those achievements.

Published at regular intervals (weekly, monthly and so forth), employee magazines are much like ship and station newspapers.

Customer

Customer magazines are produced to remind their readers of the desirability of using a company's product or service.

Stockholder or Corporate

Stockholder or corporate magazines are published to inform a company's shareholders about policy and financial matters concerning that company.

Sales

Sales magazines are publications designed to help a company's field representatives make more sales. These publications contain suggestions on generating customer interest in some product or service and tips on closing sales. They might carry an evaluation of a successful sales campaign and offer advice on ways for the sales force to use it in connection with their wares. Sales magazines also are useful in keeping a sales force abreast of changes and improvements in their products and for motivating personnel with articles on positive thinking.

Dealer

Dealer magazines are publications produced to maintain an open channel of communication between a manufacturer and each independent dealer. They deal largely with facts about the manufacturer's product.

Technical Service

Technical service magazines are publications that contain technical information necessary for using or repairing a manufacturer's product.

Many of the larger companies, and some of the smaller ones, have their own printing facilities and editorial personnel so they can produce their publications "in house." Others employ only editorial personnel and "farm out" the printing requirements. Still other companies contract to have their magazines produced entirely by outside publishers. Regardless of the system used, the masthead of each magazine contains the name and address of the editor to contact about submitting material.

SERVICE-ORIENTED MAGAZINES

Service-oriented magazines are those magazines produced primarily for military personnel (active duty, reserve and retired), military dependents and Department of Defense (DoD) civilian employees. That is not to say that these publications have no readers outside their targeted audience. Many of the service-oriented magazines are read with interest by such people as educators, contractors, former military personnel and "friends of the services," such as Navy League members (fig 4-2).

However, Navy Journalists writing for these magazines should remember to direct their articles to the primary audience. Service-oriented magazines

Figure 4-2.—Services-oriented magazines provide a host of opportunities to tell the Navy story.
(Photo by JOCS (AW) Jon Gagné.)

may be compared with the special interest publications in the consumer magazine class. They are directed at a specific group of readers with a common interest (concern about the military establishment). Some of these magazines are intended for readers in all the armed forces (*Defense News*), while others are directed at a single service (the Navy's *All Hands*). Still other service-oriented magazines are published for a select group within a broad specific group. Examples of this type of magazine include *The Navy Supply Corps Newsletter* and *Mech*. These publications could also be compared with trade journals in the company publications class.

Service-oriented magazines are generally divided into the following three categories:

- Internal
- Association-produced
- Commercial enterprise

While most government agencies and all of the military services produce publications for their people, here we are concerned only with those published for the Navy. Therefore, all references in this manual to internal magazines are only to those produced for an audience connected directly with the Navy. These internal magazines include publications produced by

the DoD, Department of the Navy (DON) and individual naval commands. These publications can also include any magazine published by a command in another branch of service if at least one of the Navy's publics is a part of its targeted audience.

Internal

Internal magazines are financed with appropriated, or in some cases, nonappropriated funds. They are issued periodically—most are monthly publications—and contain no advertising. They are distributed free to their intended readers throughout the fleet. However, these publications are available to anyone in or out of the service and may be obtained at prescribed subscription rates. Internal magazines are edited (except for articles submitted by outside sources) and written by military personnel and civilian employees of the federal government (fig 4-3).

Examples of internal magazines are *All Hands* (mentioned earlier), *Naval Aviation News*, *Link* (a quarterly magazine dealing with enlisted personnel information), and *Navy Family Lifeline* (a newsletter of educational and informational articles and feature stories of special interest to spouses and families). See figure 4-4.

Figure 4-3.—Link Magazine and Prospective are two internal magazines published by the Bureau of Naval personnel.
(Photo by JOCS (AW) Jon Gagné)

Figure 4-4.—All Hands, Surface Warfare and Naval Aviation News are three of the premier internal magazines.
(Photo by JOCS (AW) Jon Gagné)

Association-Produced

Association-produced magazines are service-oriented periodicals sponsored primarily by associations interested in the military establishment and the individual services. In most instances, these publications are written and edited either by employees of the DoD or privately employed individuals. Most magazines in this category carry advertising to help with their financing.

Examples of association-produced magazines are *Proceedings*, sponsored by the U.S. Naval Institute,

and *Sea Power*, sponsored by the Navy League of the United States.

Commercial Enterprise

Commercial enterprise magazines are those published by private enterprises. They are financed by advertisers who want to reach a military audience.

Examples of commercial enterprise magazines are *National Defense*, *Military Living*, *Off-Duty* and the *Times Magazine*. Magazines in this category are also listed with the special interest publications group in the consumer magazines class.

Commercial enterprise and internal magazines provide the most probable markets for most Navy stories. However, all possible markets should be considered when you are developing a story idea.

MAGAZINE ARTICLES

LEARNING OBJECTIVE: Analyze the types of magazine articles and recognize the methods used in researching ideas for the various types.

Magazine articles are the stories, news items and other copy, regardless of length, that appear in magazines. Before publication, any such material is called a **manuscript**.

Magazine articles may be either fictitious or true, and much of the information presented in this chapter can be applied to both types. However, since Navy Journalists are expected to deal with facts, only nonfiction writing is specifically addressed here and throughout this training manual.

The major difference between a magazine article and a newspaper story is the style in which each is written. Matthew Arnold, a famous nineteenth century English poet and literary critic, once described journalism as “literature in a hurry.”

Arnold was not trying to belittle newspaper writers with that remark. He was merely noting that the obvious difference between news reporters and other writers is the breakneck pace at which newspaper journalists so often must operate. Newspaper reporters, by the very nature of their jobs, must carry the burden of unrelenting and monotonous regularity intensified by the pressure of deadlines. Working under those conditions could hardly be considered ideal for creative writing.

Now, however, even newspapers have discovered the magazine style, and many are even adopting its format.

Most newspapers report hard news in the traditional, inverted pyramid style but have had to use new tactics to compete with television coverage of timely news events. Their solution has been to provide in-depth coverage and a lengthy analysis of the news.

Many newspapers also have started carrying any number of feature stories in their pages on a regular basis to boost circulation. Some newspapers now publish almost nothing but features, especially photo features. And almost all major dailies with large Sunday editions publish their own magazine inserts or carry a syndicated magazine insert, such as *Parade*.

Consequently, when you are searching for a market for your manuscripts, you may often need to look no further than your local newspaper. Remember, however, that newspapers are published more frequently than magazines, and therefore, they usually are governed by stringent deadlines.

“Traditional” magazines, on the other hand, impose no such deadlines. It is true that news magazines, financial publications and a few other periodicals have a need for timely material. However, those are not the magazines you are likely to approach about running your Navy stories.

While all magazines, of necessity, have deadlines to meet, they are only printers’ deadlines. Most magazines carry material compiled 2 to 3 months in advance of publication.

Sometimes a magazine staff member is given a deadline for writing an article for a particular edition, but usually outside writers are faced with no such constraints. Any idea you may have is yours to develop at whatever pace you choose. You can allow ample time for research, time for the actual writing and more time, as necessary, for rewriting. You can leave the project and go on to other things, returning when you are ready. Then, when you are satisfied with your article, you are the one who decides it is completed. Theoretically, all this is done before anyone else knows the article is in the offing. In effect, it does not exist until you are ready to submit it.

Realistically, you, working as a Navy Journalist, are likely to be given an expected completion date for a magazine article assigned by your PAO. Also, after communicating with a magazine editor about a proposed article, you may be told that the article is

needed before a particular date. Those instances could be thought of as deadlines, but not very rigid ones. They mean glancing at a calendar, not watching a clock. This more leisurely pace of writing allows the marked difference in style between standard newspaper stories and magazine articles. Basic news stories, you will recall from chapter 2, are written in an inverted pyramid style. This form is preferred by newspapers and electronic media news departments because it presents all of the important facts at the beginning of a story. If there is not enough time to write or enough space or time to publish the complete story, a paragraph or two will usually suffice.

Since magazine articles are printed in their entirety, there are no requirements to put all of the important details “up front.” Therefore, magazine writers may use any format they believe best suits the material being presented. This allows the writers wider latitudes of expression and creativity.

The magazine form also gives writers the opportunity to be more thorough in their storytelling. Both news stories and magazine articles deal with facts. However, while newspapers usually present the basic details without comment (except in editorials and columns), magazines amplify those facts in depth to show how they will affect the reader. When necessary, magazines also permit their writers to provide extensive background details to enable the reader to understand the subject more fully.

A newspaper’s news has a perishable quality; its value and interest diminish as the degree of immediacy wanes. The news in magazines, although less timely, is more enduring. Many magazine articles are as informative and interesting a year after publication as they were on the day they first appeared in print. Magazine articles also are remembered longer than newspaper stories because magazines are read more thoroughly, and at a more leisurely pace, than are newspapers.

TYPES OF MAGAZINE ARTICLES

Any attempt to classify all of the forms of magazine articles would probably prove to be inadequate. However, certain characteristics do tend to identify seven general categories. These categories frequently overlap, and the dividing lines that separate them often become blurred. Even so, this classification serves as a starting point for learning to recognize the various types of magazine articles. This knowledge is necessary before you can even consider writing for the

magazine industry. For our purposes, there are seven basic types of magazine articles. They are as follows:

- Personality sketch
- Personal experience
- Confession
- Narrative
- Utility
- Interview
- Featurette

Personality Sketch

The personality sketch is a short biography that includes an individual's achievements. The purpose of an article of this type, whether a success article or a profile, is to portray the intimate details of character and personality of someone. The person may be widely known, one who has achieved some form of greatness or someone whose life is in some way interesting or remarkable. The individual does not have to be a famous show business or political personality; this type of story could just as well be written about a Navy person.

A Navy jet pilot who adopted an entire orphanage of Japanese children was the subject of an article of this kind. Another dealt with a Sailor aboard a destroyer who spent his reenlistment bonus on football equipment so his shipmates could compete against the crewmembers of larger Navy ships. Still other sketches have been written about Navy scientists, combat heroes, chaplains, test pilots and athletes.

Personal Experience

Unusual adventures, unique accomplishments, rare travel experiences and countless other personal experiences lend themselves to treatment in this type of article.

"My 60 Days Under the Sea in an Atomic Submarine," "I Fly With the Blue Angels," and "I Walked on the Moon" are typical titles of personal experience articles.

Thousands of Navy men and women have had exciting personal experiences they might have developed into good magazine articles. Quite often, however, they do not have the ability, the time or the inclination to write these experiences on paper. Nevertheless, they usually will talk about their

experiences, which can provide a good story opportunity for a journalist in search of ideas.

When you write this type of article, use the "as told to ..." byline. You should also use caution when writing in the first person. The frequent use of "I" can become or appear egotistical.

Confession

The confession article is not necessarily a "shocker" or scandal story. Instead, it is an "inside story" of conditions or problems normally unfamiliar to the average reader. The confession article often involves handicaps or disadvantages that are overcome by determination and common sense.

Incidents related in confession articles are often typical of everyday life. A spoiled, rich kid learns discipline and responsibility aboard a Navy destroyer. A midshipman's determination to overcome a speech defect saves his Navy career. A young man cures a morbid fear of water by joining the Navy. Subjects like these have been used in confession articles. The most noticeable characteristic of the confession story is the intimate, confidential tone in which the writer seems to be personally revealing a secret to the reader. Although the subject matter is personal, it must evoke an emphatic response from the reader.

Humor should not be overlooked in this type of article. An individual's willingness to tell the story shows that he or she is not ashamed. If humor can be injected into the account, it indicates an objective approach.

Some subjects are best told when given a humorous treatment. Many interesting articles about common phobias, such as a visit to the dentist, have been written that way. This approach often helps readers to see that most of the fear is unfounded. If the humor is skillfully handled, the readers will probably be amused.

Keep in mind, though, that humor must fit the situation. Flippant treatment of serious or distressful subjects will likely alienate your readers.

Narrative

The narrative is especially suitable for writing about Navy subjects. Sharp characterization, vivid description, dialogue, action and suspense are skillfully woven into the framework of a narrative article to dramatize the facts. However, the facts must be adapted to this type of treatment. The writer does not invent them, exaggerate them or embellish them in

any way. The story must be authentic even in the smallest detail.

The real life exploits and adventures of Sailors the world over, are told in magazine articles using the narrative approach. A heroic rescue, an epic battle, a dramatic struggle against the elements, a display of bravery and determination in the face of overwhelming difficulties are all subjects that may be developed into narrative articles.

Careful research is important in writing the narrative article. This is especially true if it is about an event in which many of the magazine's readers may have participated. An important error or omission will immediately be noted by these people, and they will then be skeptical of the entire article. Also, the writing should be colorful and fast-paced. Otherwise it may sound like a chapter out of a history textbook.

Utility

Any process, product, method or idea that will help the reader become wiser, healthier, wealthier or happier is a subject for the utility article. Also called the "how-to-do-it" article, the utility article is generally shorter than most other articles and the writing is usually expository or explanatory.

The Navy offers a wealth of ideas for the utility article. At one time or another, practically everyone has devised a scheme to improve a job, working conditions or equipment. These ideas are especially valuable if they can be tailored for a specific magazine. There are thousands of trade and employee magazines constantly looking for material of this type. Editors of *Popular Science* and *Popular Mechanics* build their entire magazines around this type of article.

The utility article can be compared to a set of instructions presented in an interesting and lively manner. Writers should ask themselves the questions they feel readers are most likely to ask, then answer them clearly and simply. Even though some readers may be experts, writers must assume that every reader is unfamiliar with the information and provide complete details. A routine set of instructions for building a simple cabinet can be interesting if it is presented properly.

You can use the first, second or third person in writing this article. The personal experience approach can be very effective in the utility article. The third person style should be used only if the idea presented involves dramatic or entertaining situations. The most

common approach is to use the second person, imperative voice (You fit the wrench ...).

Interview

Interview articles present questions and answers that offer a subject's views on a given topic. Little background information is given in the article if the subject is widely known to the readers and the emphasis is on the topic of discussion. The interview requires much advance planning, however, and the writer should research the subject thoroughly before conducting the interview. Each edition of *Playboy* presents an excellent example of the interview article.

Featurette

The featurette is probably the most popular and best-selling short article found in magazines today. It is short and simple, and it contains the element of oddity or humor and sometimes both. The purpose of the featurette is to entertain.

"Humor in Uniform" and "Life in These United States," are regular sections in *Reader's Digest* and are good examples of the featurette. Nearly every magazine carries at least one anecdote as filler material in each issue.

RESEARCHING AN IDEA FOR A MAGAZINE ARTICLE

Every person, place, event or thing is a possible source for a magazine article. What one person sees daily and takes for granted, another person with a well-developed eye for the interesting and unusual often can turn it into a successful article. The idea sources and material concerning feature writing discussed in chapter 3 also apply to magazine writing.

The Navy is a fertile source for subjects and ideas you can develop into good magazine articles. All you have to do is look around you. Better yet, thumb through some of the current issues of the leading magazines or visit the magazine's world wide web site. See what civilian professionals have written on the subject.

The sea, Sailors and ships have fascinated readers for centuries. The modern saga of the sea and the men and women of the U.S. Navy is as thrilling as anything found in fiction. In many cases, the factual accounts of the modern Navy far surpasses fiction material. Atomic-powered ships, supersonic aircraft, intercontinental ballistic missiles, earth satellites,

probes into space and similar topics have stimulated the imagination of hundreds of writers. Yet, countless story ideas about those subjects are still available to you.

Opportunities in the magazine field for Navy Journalists, or for that matter, any Navy man or woman with writing talent, are almost limitless. And to get started, one needs only to begin thinking.

Any magazine article, whether for a glamorous nationwide consumer magazine or for one of the Navy's internal publications, should begin with a good idea supported by a statement of purpose. An author without a purpose for an article easily loses sight of the intended goal. If an article would serve no purpose, the likely result would be wasted time and an unintelligible product.

Many beginning writers fail to narrow the subject to a workable idea. A sharp focus on a story idea is extremely important. The focus could be on an individual, an episode or theme, but it must be clearly defined.

The next step should take you, the writer, to the *Reader's Guide to Periodical Literature*. This guide is a cumulative index of published authors, subjects and titles that are current to within two weeks of its publication. When you use this reference, pay particular attention to the most recent coverage (by all publications) of your selected subject. This will help you determine if your idea is still fresh. Also, take notes to help you when you research information for the article.

You may also need to use some specific indexes for research. The *Air University Library Index to Military Periodicals*, for example, references all items that have appeared in service-oriented publications. The Internet can give you thousands of references and related stories that have been published. Other special indexes, including the library card catalogue, the *Cumulative Book Index*, and the *Book Review Index*, address subjects covered in a variety of other periodicals. You can also consult biographical dictionaries, encyclopedias, newspapers and pamphlets to learn about a particular subject. It is not uncommon for a writer to spend days, weeks or even months collecting information before an interview or visit.

One writer, preparing to write a personality sketch on a famous composer, spent 6 months doing research before he felt ready to interview his subject. During those 6 months, the writer spent three months reading

about symphonies. He spent another two months studying that particular composer's works and a final month talking to people who knew the composer.

Obviously, you will not spend 6 months researching every magazine article you write. However, in most cases, you will need to do some extensive research. The in-depth nature of most magazine articles requires that the writer thoroughly understand the subject he or she is presenting. Unless you are writing from personal experience, you must be prepared to conduct whatever research is necessary to give your article the degree of authority it requires (fig. 4-5).

Studying Magazine Styles

Knowing the markets for magazine articles is almost as important as knowing your subject. The best-written manuscript serves no purpose tucked away in a file cabinet or desk drawer. And the best-conceived idea for an article is of no value unless it is presented in an acceptable manuscript.

Studying magazines can solve both of these problems. Your research will tell you which magazine publishers are interested in your subject and the style in which they want articles to be written.

As you examine the magazines, you should be alert to the literary style or approach a magazine takes in presenting a subject. For instance, several magazines might handle a piece dealing with the Defense Information School (DINFOS) but each would present it in an entirely different way. The *Educational Review* would probably want to know the concepts and techniques of instruction, the *RCA Electronic Age*

Figure 4-5.—Magazines vary in size, content, and design.

(Photo by JOCS (AW) Jon Gagné.)

might be interested in the use of radio and television equipment, *All Hands* would likely prefer a story about the faculty and students and *Parade* might want emphasis on the educational angle and benefits to the individual.

In addition to the Internet, several publications dealing with the needs and requirements of magazines are available to assist you in your research. One such book is *Writer's Market*, published annually by Writer's Digest Books of Cincinnati, Ohio. *Writer's Market* contains a listing of nearly all consumer magazines and business journals published in the United States and Canada. Along with those listings is the following information:

- Mailing address of publication.
- World Wide Web Site Address.
- Names(s) of editor(s).
- Frequency of publication.
- Circulation.
- Demography of readers.
- Approximate number of manuscripts purchased per issue (if any).
- Method of payment (flat rate for manuscript, pays per line of copy, pays per word, pays percent of magazine royalties, pays in magazine copies, pays nothing).
- Rights purchased (all rights; first North American serial rights; simultaneous, second serial (reprint) rights; one-time rights; and so forth).
- Whether by-line is given.
- Description of material desired.
- Description of material not desired.
- Whether photos are desired, and if so, payment rates.
- Minimum and maximum lengths of manuscripts.
- Lead time for submission of season and holiday material.
- Whether unsolicited manuscripts are accepted.
- Whether previously published submissions are accepted.

- Whether simultaneous submissions are accepted. (Some magazines, especially regional ones, will consider such submissions if the offered manuscripts are not being sent to other publications in their state or geographical area.)
- Additional tips considered appropriate by various magazine editors.

You should keep in mind that most magazine editors have very specific ideas about material for their product. Any deviation from their expressed standards is almost certain to result in a manuscript's rejection.

The editors, especially those of the major, nationwide publications, can also be very selective in accepting material. Some will reject, out of hand, any offer of material from unpublished writers. However, the editors of many other publications encourage submissions by "new" writers. This is particularly true of newly created, special interest magazines and many of the literary publications, or "little magazines," as they are sometimes called.

For Navy Journalists this preliminary research is made much easier by the valuable assistance of the regional Navy Offices of Information (NAVINFOs) or Public Affairs Centers (PAC). NAVINFOs and PACs are field activities of CHINFO.

IMPORTANT NOTE: Manuscripts written as part of your official duties for civilian magazines *must* be marketed by a NAVINFO. You may send your manuscripts to Navy-produced magazines (such as *All Hands* or *Link*) without NAVINFO involvement, but the aforementioned research rules apply.

Before sending your manuscript to a NAVINFO, you should call or write that activity, explain your story idea, then follow the guidance you receive. The NAVINFO will contact those publications most likely to use a particular story and notify you when and if a market is found.

If the idea has been accepted, you will be notified by the NAVINFO. They will then give you information similar to that contained in the *Writer's Market*, mentioned earlier. Your NAVINFO will give tips on the writing style preferred, advise you on when to submit your material and make suggestions for the length of your manuscript. The NAVINFO will also tell you if a commitment has been made by a magazine's editor to publish your story or if it is to be submitted on speculation.

The NAVINFO deals with the various magazines through correspondence called queries. In this

context, a query is a letter from the writer, or in this case, the NAVINFO, to a magazine's editor. The query briefly describes a proposed article, and if required, contains up to three clips of the writer's previously published articles.

A favorable response to the query most likely will contain specific style tips—a list of do's and don'ts—on writing for that magazine. A large number of publications have their own styleguide booklets that are sent to potential writers. Early in your research of magazines or from the information provided by your NAVINFO, you gained a general insight into the style and editorial content of the magazine ultimately selected. Now you need to begin studying that magazine in earnest. If possible, get three or four different issues and read them thoroughly. Also, study the tips or styleguide supplied by the magazine's editor through your NAVINFO. Observe the character of the language. Note whether it is scholarly or adventurous, technical or general, personal or formal, humorous or serious. You must also look for taboos on subject matter and content. Some magazines will not print slang, for example, and some will not mention their competitors.

When your research is completed, your story idea firmly fixed in your mind and your market clearly identified, you are ready to begin writing.

After having a few articles published by the same magazine, you will develop a feel, or sense, for what that publication wants. Then you will be in a position to work leisurely on manuscripts whenever story ideas occur and you will be able to contact your NAVINFO about ready-to-publish material.

You should also give internal magazines, such as *All Hands*, the same intense study you give commercial publications. Navy internal magazines, like their civilian counterparts, have their own styles. Therefore, contributors, especially Navy Journalists, should be aware of them and prepare their manuscripts accordingly.

While the editors of internal publications are more inclined to edit weak or unstylized copy than their civilian counterparts, you should refrain from making it necessary. You are expected to be a professional and anything other than your best effort reflects poorly on you and your command.

As mentioned earlier, you are authorized to submit articles directly to Navy internal publications in the same manner your command makes routine news releases. You may also deal directly with those

publications while you are developing a story idea, either through the mail or electronically via the Internet. Although a formal query is unnecessary before submitting your manuscript, it never hurts to let the editors know what you are planning.

Outlining Magazine Articles

Whether you are a seasoned writer or a novice, all magazine articles should begin the same way—with an outline. Experienced writers may use rough, written outlines or formulate them in their minds, but beginners are wise to continue using the formal, written method.

An outline is a valuable aid in magazine writing. It helps you organize and evaluate your information and it makes writing an article easier and faster. You should develop, thoroughly, the outline and include all the specific details, explanations and anecdotes that contribute directly to the article you are writing.

Once you prepare an outline, concentrate strictly on the actual writing of your article. You already will know what facts to include and where and how to use them. The basic magazine article outline may be divided into the following five parts:

1. **Purpose.** State the reason or reasons for writing the article and what you intend to accomplish. This sets a course to follow once you begin writing.
2. **Market analysis.** Study surveys that show which magazines are read by the population segment you wish to reach with your article.
3. **Markets.** List the magazines identified in your market analysis that are most likely to publish the article you are planning to write. Follow this up with queries to those publications. (Note: Parts 2 and 3 are performed by a NAVINFO when dealing with civilian magazines.)
4. **Sources.** List the people, reference books, magazines and so forth, from whom or from which you expect to get the information needed for your article.
5. **Plan of development.** List pertinent facts, major areas of coverage, subtitles, anecdotes and so forth, in the order you want to present them.

WRITING A MAGAZINE ARTICLE

LEARNING OBJECTIVE: *Recognize the fundamentals of writing a magazine article and evaluate its components.*

Except for style, most of the rules and information concerning the fundamentals of newswriting presented in chapter 2 of this NRTC also apply to magazine writing. You must be able to recognize the 10 news element categories examined there. The presence and intensity of any of those elements, other than immediacy, determine the newsworthiness of magazine articles as well as news stories. Furthermore, you must apply the “ABCs of Journalism” discussed in chapter 2—accuracy, attribution, brevity (to some degree), clarity, coherence, emphasis, objectivity and unity. You should also understand and follow the guidelines provided under the heading “The Language of Newswriting.”

As the categories of magazine articles overlap, so do the methods of writing used in each. However, a common pattern can be found.

A major element of most articles, one that gives flesh and blood to the story, is the anecdote. An “anecdote” is defined as any specific, short, significant story or incident.

Generally, a magazine article can be divided into four basic components:

- The title
- The lead
- The body
- The conclusion

THE TITLE

The title of a magazine article should tell the readers the nature of the article. It usually features a short, terse statement designed to attract their attention or to arouse their curiosity. The title should entice the audience to read the article immediately.

A title, like the article itself, should be slanted or directed toward a particular market. Each magazine has its own title requirements for style, length and typographical arrangement. Some magazines prefer titles that summarize the information in the article. Others want descriptive titles. Still others prefer titles that make striking statements. And some favor titles featuring questions, quotations, direct appeal or alliteration.

In developing titles for their articles, writers must be honest. They should not mislead the reader with

facts not supported by the articles, and they should avoid exaggeration or sensationalism.

The title should convey the tone and spirit of the material featured in the article. Declarative sentences with concrete nouns and active verbs are best.

If you have not thought of a good title when you begin writing an article, do not worry about it. Few writers title their stories in advance. Usually, the facts will suggest something suitable as you write. Often a strong sentence in your copy will provide the exact title you need.

THE LEAD

The lead of a magazine article is similar to the lead of a news story, except it is usually longer and nearly always more difficult to write. The lead may run only one paragraph in length, or it may run as much as 10 percent of the entire article.

Whatever space you allot to your lead, it must accomplish the following objectives:

- Indicate the central idea to be conveyed in the article.
- Contain a hint of the spirit and movement of the article.
- Locate the subject as to time and place.
- Show any relation that may exist between the facts and the reader.
- Generate enough interest to make the reader want to read the rest of the article.

Leads for magazine articles, like those for news stories, should be written in a manner suitable for the subject matter. The lead is the most important part of a magazine article. If it fails to sustain the readers’ interest, they will not read the article. Therefore, many professional writers spend nearly as much time developing a good lead as in writing the remainder of an article. As trite as the expression may be, a good writer knows that “a story well begun is half done.”

THE BODY

The title of a magazine article attracts an audience’s attention. The lead arouses curiosity, stimulates interest and whets the readers’ appetite for more facts. The body of the article must keep the readers interested.

Keeping your audience interested for two or three thousand words is a tough job. To do this, you must carefully weigh every word, every sentence and every paragraph. The facts you use must be not only interesting in themselves, but they must be presented in an interesting manner.

The body of a narrative or personal experience story is probably the easiest to write. All you have to do is relate the details in the order in which they happened. With this approach, you can depend on the action to hold the readers' interest. However, an article that contains no action and only presents straight, factual information is harder to write. Because the facts themselves are constant restrictions, you must use skill and imagination in presenting them. The facts must flow from the article naturally, without awkward pauses or sudden changes in direction.

In all magazine articles, paragraphs should be written so they interlock. The end of one paragraph should lead naturally into the beginning of the next. Transitions should be used in such a manner that the readers are not even aware of them. The key for you to make the body of the article interesting is in appropriately inserting anecdotes, specific examples and hypothetical situations. These devices help illustrate points and emphasize important facts.

THE CONCLUSION

A magazine article should end as dramatically as it began. When appropriate, use an anecdote that typifies the main points presented in the body. Surprise endings also work well. The conclusion should neatly and succinctly tie together all the threads of the article and bring it to a smooth finish. It should make the readers glad they read the article and leave them with the impression you wanted to make when you stated the article's purpose in your outline.

TIPS ON MAGAZINE WRITING

Along with studying the information presented here, you should read as many magazine articles as possible. Carefully observe how the material in the various types of articles is organized. Be aware of the different styles used in different kinds of magazines when they print similar stories.

Note, especially, the leads written by successful writers. Examine their sentence construction—the manner in which they “turn a phrase.” Then try writing a few leads and short stories of your own. To see which feels most comfortable to you, emulate some of the

techniques of those published writers you have been studying. Experiment! Even with the vast number of magazines available to writers, the market is still highly competitive. The same factors that allow magazine writers to be creative also demand it. Therefore, the ability to write skillfully is essential to your success in this field. And that skill can be developed, through your willingness to learn and your desire to write.

MAGAZINE LAWS

LEARNING OBJECTIVE: *Determine the laws that apply to magazine writing.*

While Navy Journalists are not expected to be legal experts, there are a number of laws that merit your attention.

All writers should be aware of laws concerning defamation, fair comment, the right of privacy, copyright, fair use of the writings of others and plagiarism. This is especially true for magazine writers. The nature of their work makes the possible violation of those laws ever present, and for some, very tempting. Special care must always be taken to avoid these violations.

One area in which you must be particularly cautious is in writing articles containing personal commentary, where a strong possibility of defamation often exists. Another area of concern is in writing articles about people who do not want the attention. In articles of this type, you run the risk of invading someone's privacy. And finally, make sure your research is for information, not for someone else's phraseology. Creative writing means being original. Do not be guilty of copyright infringement or plagiarism. Also, remember that under U.S. copyright laws, **anything you write on government time cannot be copyrighted**. See chapter 10 for further information.

Chapter 10 of this NRTC addresses the subjects of libel, the right of privacy and copyright laws. An understanding of that material will give you sufficient knowledge of those laws and will allow you to write without worrying unnecessarily about them. However, if any doubts or questions arise about those laws, do not hesitate to contact a legal officer for advice.

If you want to write for commercial publications and receive payment for your efforts, you must observe certain rules.

Your writing and research must be done on your own time (after normal working hours or while on leave). It must not interfere or conflict in any way with regularly assigned duties and may not be done in connection with official duties.

Access to information sources, such as public affairs offices, is available to off-duty Navy personnel just as it is to civilian writers. However, you should remember that any use of DON facilities, equipment or personnel is permitted only in connection with official Navy assignments. Additionally, restrictions on access to classified material that apply to non-Navy professional writers apply equally to you if you are writing for a commercial publication on your own time.

Your off-duty magazine writing must not conflict with the public's receipt of prompt and complete information on government activities through the usual public information media. Further, both the subject matter and the methods of obtaining it must be legal and consistent with accepted standards of conduct.

The restrictions on writing for commercial publications in connection with official duties are waived in certain cases for key DON officials. The term *key officials*, in this context, refers to flag rank officers, Navy civilian officials GS-16 or higher, and civilian or military personnel whose official assignments are of unusual prominence or authority. Those individuals may be authorized to produce by-line writings dealing with national defense plans, policies, programs or operations for specific categories of exclusive publications. Their writings may be printed in official DoD publications or magazines of other government agencies, of course. However, they may also be published, exclusively, in company publications (house organs) or commercially produced service journals, bona fide scientific and professional journals, or encyclopedias.

Few businesses are more competitive than the consumer magazine industry. Therefore, a publisher's desire for and insistence on exclusive material are very understandable. The Navy's policy, however, is to avoid favoring one publication over its competitors. It is also Navy policy to make sure all information for the general public is made available through the normally accepted public information media. This policy virtually rules out hard news or "big" stories being written as exclusives by Navy personnel and explains the restrictions on writing for commercial publications.

Still, there are official stories you can write for consumer magazines. You just need to be a little selective.

A newspaper account of a rescue at sea operation, for example, could be turned into an exciting magazine article. Even though all the basic facts had been published at the time, a stylized retelling of the event could produce some worthwhile reading.

An approach of this kind would not conflict with the general public's free access to the information. It is also reasonable for you to assume that such a story, no longer an exclusive, would still be of interest to a number of magazine editors. Numerous story possibilities similar to that one are almost always available if you are willing to look for them.

MAGAZINE REVIEW AND CLEARANCE

LEARNING OBJECTIVE: Determine the methods of obtaining a review and clearance for magazine articles.

While Navy Journalists, as well as other naval personnel, are allowed and encouraged to write for magazines, certain restrictions exist that must be considered. Permission for Navy men and women to write magazine articles is contained in *PA Regs*. Also contained in *PA Regs* are the restrictions in magazine writing, and the exceptions to those restrictions.

The restrictions apply to the subject matter of proposed articles and to dealings with commercial publications. Unless proper clearance is obtained, no commitment will be made to furnish any nonofficial publisher with an official or personal manuscript that deals with military matters or has national or foreign implications. Subject matter of that nature includes, but is not limited to, the following:

- Information of national interest
- Information originated at, or proposed for release at, the seat of government
- Information concerning foreign and military policy, atomic energy, guided missiles, new weapons or chemical, biological and radiological warfare
- Information concerning subjects of potential controversy between the military services
- Material concerning significant policy within the purview of other U.S. government agencies

- Information specially designated from time to time by the Chief of Naval Operations or higher authority, as requiring clearance

Any material about which there is any doubt concerning its security value or propriety should also be submitted for review. Manuscripts requiring review and clearance must be forwarded to CHINFO. The material

for review is to be typewritten, double-spaced, on one side of each sheet of paper and submitted in quadruplicate. Manuscripts on subjects other than those just described may be offered to a publisher without prior clearance from higher authority. However, published copies of magazine articles should be sent to CHINFO for inclusion in DON files.

CHAPTER 5

ADVANCE STORIES, FOLLOW-UPS AND REWRITES

At one time or another in your career as a Navy Journalist, you can expect to find yourself writing an advance story, writing a follow-up, or rewriting a release received from an outside source.

Producing advance stories, follow-ups, and rewrites first requires that you know how to write, and second, that you have a sharp eye for accuracy. You also must have a sound knowledge and background of the subject about which you are writing.

ADVANCE STORY

LEARNING OBJECTIVE: *Interpret the rules and structure of the advance story.*

An advance story calls the public's attention to a coming news event (created news) that would possibly be missed if it were covered as a spot news story. It answers the following questions:

- **What** is going to happen?
- **When** is it going to happen?

Advance stories are used to promote practically every scheduled, major special event. They provide the buildup and support required to attract attention, encourage participation and assure success. Few special events could succeed without the benefit of advance announcements by local media.

Suppose your command was open for public visitation. The event probably would be a complete failure if the public did not know in advance when and where it would occur, what activities were planned, who could attend, and why the public visitation was being held.

RULES

Three important rules for you to remember when writing and releasing advance stories are as follows:

- Do not shoot the whole works in the first story. In a publicity buildup, plan the release of major facts so they may provide good news pegs for later advance stories.

- Do not ruin a good thing. Advance stories must contain legitimate news, not mere publicity puffs. Provide facts that readers will find worthwhile and interesting.
- Do not overexploit an event. Schedule your advance stories over a reasonable period of time, give enough new information in each release to keep your audience interested, but do not bore them with unnecessary repetition. The scope and importance of the event will help determine the time frame required to promote it adequately. Usually, 3 to 4 weeks will be more than sufficient.

STRUCTURE

Table 5-1 shows a typical example of an advance release that might be used to announce an Armed Forces Day public visitation. The first release should contain the bare information essentials. Subsequent releases should elaborate on the basic facts presented in the initial announcement. The actual number of advance stories is determined by what you have to tell. Each story should build up to the next one, with the most important news pegs timed for release during the week of the scheduled event.

Naval Air Station Crevalle will open its gates to the public on Saturday, May 15, in observance of Armed Forces Day.

The announcement was made today by Capt. Rosetta P. Stone, commanding officer of the station. Capt. Stone said the gates will be open to visitors from 10 a.m. to 5 p.m., and the general public is invited to attend. Parking facilities will be available on the station. Special buses are being scheduled for those who wish to use public transportation.

The theme for this year's Armed Forces Day is "The Modern Military Machine." Naval Air Station Crevalle will join with thousands of other military installations throughout the world in highlighting this theme.

The main attraction at the public visitation will be an hour-long performance by the Blue Angels, the Navy's famous flight demonstration team. Also

planned are a number of displays and exhibits highlighting the great strides made in the development of naval aviation during the past 80 years.

Table 5-2 shows examples of leads to advance stories following the initial announcement.

FOLLOW-UP STORY

LEARNING OBJECTIVE: *Interpret the purpose, reader considerations and structure of the follow-up story.*

Like advance stories, follow-ups are part of an overall story. In many news situations, there will be important or significant developments in a story already released. These news developments must then be released to update the original story. This method of reporting is referred to as **follow-ups**, which, as the name implies, follow up the facts presented in the initial spot news story.

READER CONSIDERATIONS

In writing a follow-up story, you must consider the following two distinct groups: the reader who has read the original story and the reader who may not have read the original story. Using this consideration as a guide,

your follow-up should be written so as not to bore the former or confuse the latter. You can satisfy the requirements of both readers by using the follow-up story structure explained and diagramed in figure 5-3.

STRUCTURE

As shown in figure 5-1, the follow-up story contains three distinct components—the lead, tie-back and body. These three components form the structure of the follow-up story that is covered in the following text.

Lead

The lead of a follow-up serves the same purpose as the lead in any other story. In a follow-up story, however, make sure your lead contains a fresh news peg, a new angle or an entirely different approach from the one used in the original spot news story to which it is related.

Tie-Back

The tie-back consists of one or two paragraphs located between the lead and the body of the story

Table 5-2.—Subsequent Advance Story Leads.

<p>The Blue Angels, the Navy's flight demonstration team, will provide an exciting hour-long program of thrills and precision flying at the Armed Forces Day public visitation at Naval Air Station Crevalle Saturday, May 15.</p> <p>Flying single-seat F/A-18 Hornets, the Blue Angels have been thrilling fans of Naval aviation. ...</p>
<p>A naval aviation "air museum," consisting of 20 aircraft that have played a major role in Navy history during the past 80 years, will be displayed at the Armed Forces Day public visitation at Naval Air Station Crevalle Saturday, May 15.</p> <p>Included in the air museum will be. ...</p>
<p>The former Secretary of the Navy, Jay A. Hawker, will be the guest of honor at the Armed Forces Day public visitation at Naval Air Station Crevalle Saturday, May 15.</p> <p>Now the president and CEO of the CompuTronics Computer Corporation of Tenaflly, N.J., Mr. Hawker. ...</p>
<p>A display of naval aviation ordnance, including exhibits of the powerful Phoenix missile and other air-to-air and air-to-ground missiles, will be displayed Saturday, May 15, during the Armed Forces Day public visitation at Naval Air Station Crevalle.</p> <p>Capt. Rosetta P. Stone, commanding officer of the air station, believes this Armed Forces Day celebration will be the best in the 55-year history of the air station. "I am very excited about. ...</p>

which contains a brief but clear synopsis of the information presented in the original spot news story. The tie-back is used to refresh the memories of those readers who saw the original story and to update those who did not see it.

Body

The body of the story simply presents details of all new developments in the situation. It is usually written in the inverted pyramid style described in chapter 2.

PRINCIPLES OF REWRITING

LEARNING OBJECTIVE: *Recognize the basic principles of rewriting a story in terms of improving copy, updating the story, transforming informal reports, localizing, combining stories and shifting emphasis.*

The principles of rewriting are the same as those for good newswriting. If a story does not conform to acceptable newswriting standards, it should be rewritten and made to do so. In other words, you take what someone else has written poorly and convert it into usable news copy.

When you are assigned to a command publication, such as a ship or station newspaper, you will find that a certain amount of your material comes from contributors who do not write in journalistic style. Other material comes to you as handouts and from

outside sources, such as clipsheets, naval messages, directives and official correspondence. If you want your publication to contain readable and consistently good material or if you have a local angle and want it to be accepted by commercial news media in your area, it is often necessary to rewrite it.

The following are six basic reasons for rewriting copy:

- To improve poor copy
- To update material
- To transform informal reports into properly written news stories
- To localize general information
- To combine two or more stories
- To change story emphasis

IMPROVING COPY

Often, a person's first attempt at writing a story produces dismal results. Some members of a public affairs office staff may not be thoroughly skilled in the writing craft. Also, material for intended release is often received from other staff offices or departments. These articles frequently need the professional touch of a rewrite reporter. A rewrite reporter organizes a

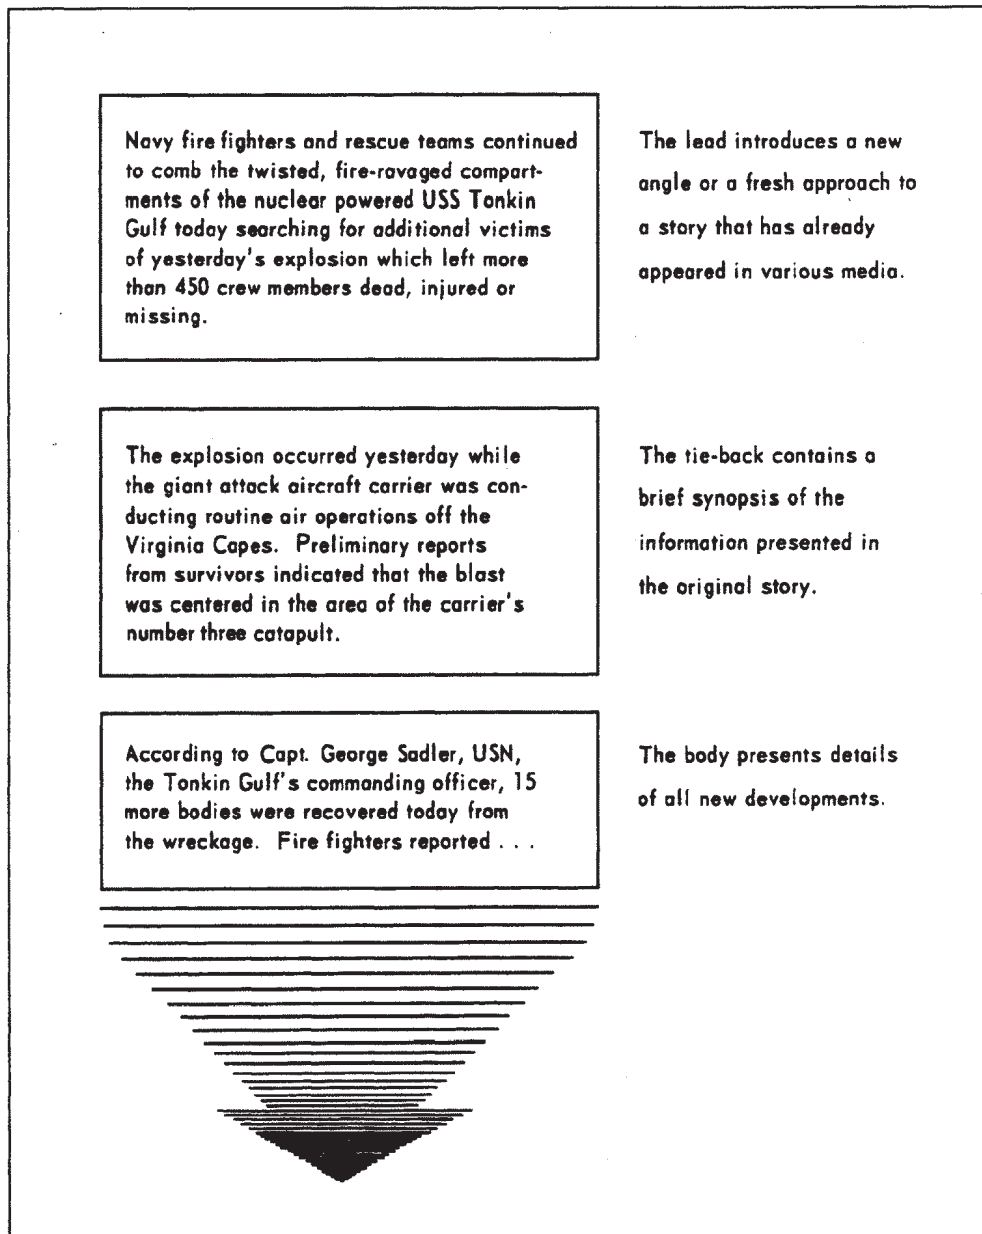

Figure 5-1.—Follow-up story structure.

poorly written, improperly arranged item into a sequentially logical finished product.

A rewrite reporter may have to turn a straight news story into a feature. In this event, the rewriter often needs to acquire additional information and can expect to spend some time on the telephone—or in a face-to-face interview—before a finished product can be turned out.

There are times, too, when the rewrite reporter may have to convert a feature story—or a poor attempt at a feature—into a news story. Therefore, a reporter should be proficient in both types of writing before assuming a rewrite assignment.

One of the most frequent faults of badly written copy is the writer's failure to give ample play in the lead to the dominant news element of the story. The rewriter must dig through the story, find the proper lead, put it at the beginning where it belongs and, finally, organize the remainder of the story in coherent form.

UPDATING THE STORY

Often, the rewriter must update a story that has already been printed. So naturally, this person needs a fresh angle to perform this feat. For example, assume that a military aircraft crashes with three people aboard. Two crewmen are killed and the third is

missing. A story based on these facts would be released as soon as possible. Then suppose the third man is still alive, that he had managed to parachute from the falling airplane, had made his way back to a highway, caught a ride, telephoned the base and reported his experience. The news of a survivor is the fresh angle needed by the rewriter to update the story of the crash.

TRANSFORMING INFORMAL REPORTS

Another reason for rewrite is to turn an informal report, such as telephoned information, into a properly written news story.

Cooperation between the JO in the office and the JO on the scene is important to the Navy, especially during times of fast-breaking news events, such as those experienced during a major accident or a natural disaster.

The initial release in these cases is generally compiled by one person who receives reports telephoned by reporters in the field. To make a single, comprehensive release, the office-bound JO adds background material available in office files and sometimes works with material brought back from interviews by other public affairs personnel.

Other routine news stories are handled in much the same fashion, without the hectic atmosphere and pressure of disaster stories. For example, the command's MWR petty officer may be the public affairs office correspondent for athletic events. That does not necessarily mean the correspondent brings a finished story to the public affairs office, but rather, the correspondent telephones a contact there and reports the details of some sports event, and the JO turns that report into a professional release for local media and the command newspaper.

LOCALIZING

Public affairs offices receive news from a variety of people and places. News releases from the DoD, DON, weapons manufacturers, shipyards, aircraft manufacturers and other outlets provide good sources for outside news. However, this news is usually broad in scope and slanted toward a general market. Therefore, it will require a certain degree of refinement and localization to meet the needs of your local readership.

When these releases are rewritten, the local angle should be introduced in the lead and the more general aspects minimized. For example, suppose you are attached to a naval air station and receive a handout from an aircraft manufacturer stating that a new type of aircraft is in production and will soon be made available to the Navy. The release contains a wealth of unclassified information about the plane and its potentialities.

A little research on your part uncovers the fact that an aircraft squadron at your command will be one of the first squadrons in the Navy to receive and operate the new planes. You can now combine your information with that in the general release—playing up the local aspect—and you will have a story of interest to local readers.

COMBINING STORIES

In the case of combining stories, the rewriter often puts two or more stories together to make one. The combination generally results in a roundup story with the first paragraph carrying a combination lead to emphasize various news developments.

An example might be a combination of the following stories:

- A story is carried in the local paper about a hurricane that struck the area.
- A news release is issued by a nearby naval command citing several men assigned to that activity who aided victims of the disaster.
- Both of these stories, wrapped up with a fresh release about awards for heroism presented to Navy personnel by the mayor of the nearby town, nets the rewriter a multi-interest, highly readable story.

SHIFTING EMPHASIS

In Navy public affairs, it is standard policy to release the **same** story at the **same** time to **all** media. However, you will get better media mileage if you rewrite the same release several times to meet the needs of different media.

Suppose you wanted to get a certain story published in a variety of publications, such as the local papers, *Navy Times*, *Naval Aviation News*, one or more of the trade publications and several individuals'

hometown newspapers. In addition, you think the story is worthy of airtime on radio and television.

Under normal circumstances, you cannot take the time to rewrite the same story several different ways and slant it to the particular needs of different media. Yet there are occasions when this is necessary, if you want to obtain maximum coverage for a special type of story. When this is the case, you will have to keep rewriting the story in the style preferred by each of the different media.

Tables 5-3 through 5-4 show introductions to four different accounts of the same story as published in *Our Navy*, *All Hands*, *Navy Times* and one of several hometown newspapers. Although all the stories concern the rescue of a grounded LST from a coral reef in the Bahamas, note how the story is rewritten each time to present a new approach or to meet the style of the particular publication for which it was intended. Although a certain amount of additional work and effort was necessary, the rewrites resulted in 100 percent coverage.

Table 5-3.—Our Navy Excerpt

COMBINED SALVAGE OPERATIONS

SAVE THE USS LST 291

A modern epic of the sea—unequalled in recent naval annals for sheer endurance and ingenuity—was written early this year near a tiny, coral-studded island in the Great Bahamas. It involved a grounded amphibious force vessel that was rescued from a treacherous coral reef after almost two weeks of relentless and frustrating efforts by ships and men of the Atlantic Fleet.

The salvage operations, which were carried out in the storm-ridden, shark-infested waters off Eleuthera Island, involved a dozen ships, the Navy's top salvage and underwater demolition teams and aircraft that were employed for everything from the evacuation of survivors to the transportation of explosives.

Practically every trick in the Navy's salvage repertoire was used, and many new ones were thought up to cope with the unusual and near-impossible situations that hindered the immediate rescue of the grounded ship.

The curtain went up on this modern epic of the sea about 0300 on 16 March with the Little Creek-based LST 291 churning its way through the dark and murky waters of the Great Bahamas. ...

Table 5-4.—Navy Times Excerpt

TUGS, FROGMEN, TNT

FREE STRANDED LST

NORFOLK, Va. — Eleven days after running aground in the Bahamas, the shored-up LST 291 rode a two-line to Jacksonville, Fla., and the crews of at least eight vessels which helped it off the beach breathed weary sighs of relief.

In the early pre-dawn hours of March 16, the LST was homeward-bound with 118 Marine passengers and the amphibious gear they had used in the maneuvers at Vieques, P.R. Suddenly, it struck a submerged reef off James Pt., Eleuthera Is., Bahamas, and ripped a jagged hole in her hull.

Fifteen minutes after it hit, word was passed to abandon ship. Its passengers and all of its 96-man crew but a salvage detail scrambled ashore. ...

Table 5-5.—All Hands Excerpt

BLASTING THEIR WAY TO SAFETY

One of the more unusual salvage stories of the year is the tale of an LST grounded so fast on a coral reef that frogmen had to blast a 1,000-foot channel to free it.

USS LST 291 was churning its way through the waters of the Great Bahamas after completing two weeks of amphibious training exercises at Vieques, Puerto Rico.

About 1,800 yards off James Point, Eleuthera Island, the crunching of steel and stone shattered the silence of the night. The LST had hit a submerged coral reef. The grounding tore a two-foot hole in the evaporator room and twisted, warped and gashed the heavy steel skin in other parts of the ship's hull.

Water started pouring in through these openings and all of the lower compartments became flooded. Personnel were ordered over the side.

Although the nearest land was less than a mile away. ...

Table 5-6.—Hometown Newspaper Excerpt

DOING NEXT TO IMPOSSIBLE

JUST ROUTINE TO NAVY CMDR

ROBERT K. THURMAN

CMDR Robert K. Thurman, USN, the son of Mrs. R. L. Thurman of Cashmere, is earning high praise and recognition in Norfolk for his abilities as a Navy salvage officer.

His most recent accomplishment as a salvage officer was the rescue of the Landing Ship Tank 291 in the Great Bahamas after it had gone aground on a treacherous coral reef early this year.

With Thurman supervising the salvage efforts, the Navy LST was finally freed after almost two weeks of relentless and frustrating efforts by ships and men of the Atlantic Fleet.

Carried out in the storm-ridden waters off Eleuthera Island, the salvage operations involved a dozen ships, the Navy's top salvage and underwater demolition experts and aircraft that were employed for everything from the evacuation of survivors to the transportation of explosives.

But this was only one of many such operations in Thurman's long and eventful naval career. Other notable achievements for him involved the battleship USS *Missouri* and the military sea transport tanker *Wascissa*.

When USS *Missouri* went aground off Hampton Roads in 1950, Thurman was skipper of the salvage ship USS *Windlass*, which was instrumental in freeing. ...

CHAPTER 6

COPY EDITING

One of the most important and exacting jobs on any publication is that of written copy being given the final professional touch of accuracy. This job of catching and correcting inaccuracies before they can be printed and distributed is called **copy editing**.

Readers may have a high regard for a newspaper that is carefully edited, but they quickly lose respect for one that is sloppy and full of errors.

The copy editor of both civilian and Navy publications represents the last line of defense against incorrect copy reaching the reader. It is the copy editor's job to make sure copy is not printed unless it meets certain standards. The copy editor is the guardian of both style and accuracy. Always on the alert for questionable facts, ambiguous statements and violations of office policy, the copy editor must catch errors in grammar, spelling, syntax, punctuation, capitalization and so forth; cut out words or sentences that are not needed; and add copy when necessary for clarity, emphasis or continuity.

Another responsibility of the copy editor is to restore objectivity to a story in places where a writer may have editorialized, quoted out of context or inserted an opinion without attribution to a source or pertinent authority. Also, the copy editor is constantly alert for statements of a libelous or slanderous nature. (Libel and slander are covered in chapter 10.)

The copy editor of a civilian newspaper has an additional function of assigning headlines for the edited stories. Navy copy editors, unless they are editing stories for use in ship or station newspapers, have no responsibilities in this area. They could hardly be expected to know the styles, formats, and individual editorial needs of all the newspapers that receive news releases from a public affairs office. It is, however, sometimes appropriate to put a brief heading on a story to identify its subject readily.

Like any typical, beginning newswriter, the neophyte JO is dismayed to see his "literary masterpiece" chopped up, pasted back together again and scored with the copy editor's pencil. Nevertheless, two minds are usually better than one. Most experienced writers will admit that the final result,

despite its mangled appearance, is a better piece of writing.

Security is of the utmost importance in the armed forces. The responsibility for security lies with every person who, in any way, handles a story, but the copy editor sometimes represents the last defense against a possible violation. If you have doubts about the security classification of any information you receive, check it with your security officer.

This chapter acquaints you with the standard symbols and style used by the copy editor and explains the procedures, rules and guidelines of copy editing. The basic pattern of news style in this chapter follows the style of *The Associated Press Stylebook and Libel Manual* used by almost all newspapers in the United States.

COPY-EDITING PROCEDURES

LEARNING OBJECTIVE: *Identify the basic guidelines of copy editing.*

Copy editing follows a set system of procedures. To be absolutely accurate, you should read each story in the following manner:

- Read the story quickly to grasp its meaning and note its arrangement.
- Read the story more slowly and more thoroughly to correct every mistake and to add or delete material as necessary.
- Read the story again to check the copy editor's own corrections.

The final check is also intended to make sure that no new errors occurred in copy editing and that the story reads smoothly.

If the story contains too many mistakes and it appears obvious that copy editing will not improve it, the story goes back to the originating JO for rewriting, or in the case of copy received from outside sources, to a rewriter.

PREPARING THE ROUGH

The original copy of a story is known as a **rough** (fig. 6-1). Normally, it is typed double-spaced on only one side of the paper. In general, a JO follows the same format in typing a rough as in preparing a finished Navy news release. It does not have to be as neat, however, and may include penciled-in corrections, additions or deletions, as necessary. The rough obviously does not need the letterhead information usually carried on a release that is ready for dissemination. It is a recommended practice in large

offices for the author's last name to appear on the rough. This, of course, enables the copy editor (usually the PAO or the senior JO) to identify the writer.

USING SYMBOLS

To prepare copy for reproduction in its final form, the copy editor uses a special set of shorthand symbols to indicate any required changes (fig. 6-2).

For example, if the writer forgets to capitalize a letter such as the "M" and "P" in mr. poindexter, the

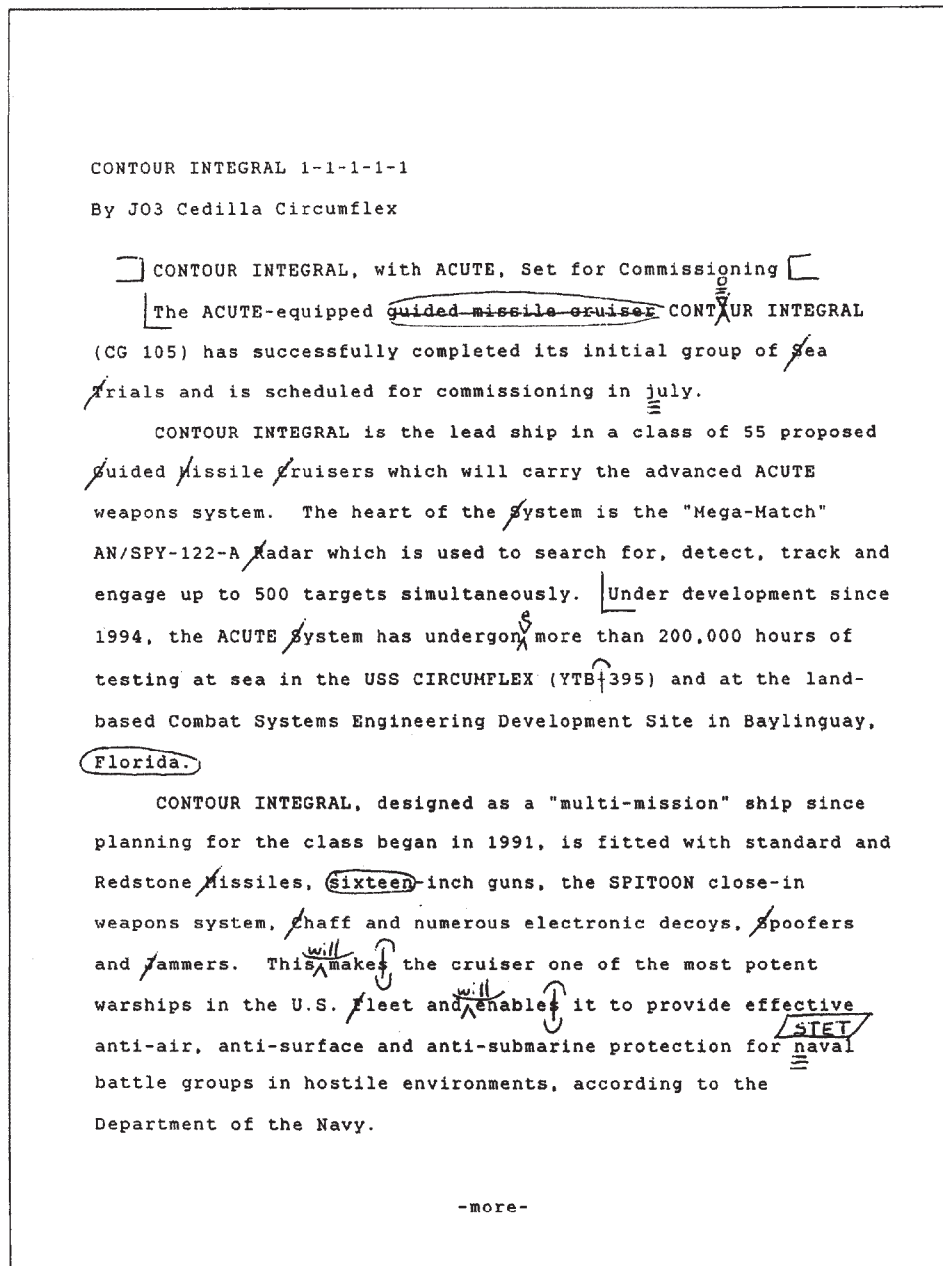

Figure 6-1.—Copy-edited story.

CONTOUR INTEGRAL 2-2-2-2

Recent reports on CONTOUR INTEGRAL in the media have described the ship as "unstable" and "overweight" and as being "unable to keep pace with a battle group." Rear Admiral Lucy Breve, CONTOUR INTEGRAL Shipbuilding Project Manager, termed those reports "absolutely inaccurate." She said, "strength and stability limits are the very foundations of effective warship design." She dismissed the overweight charge, pointing out that the CONTOUR INTEGRAL can tolerate additional displacement in excess of 1,000 tons and will right itself in all sea states. "CONTOUR INTEGRAL," (RADN) Breve continued, "meets or exceeds all Naval Architectural and Operations requirements both for intact stability and (stability) under severe damage conditions."

Recent sea trials confirmed Contour Integral's ability to meet the "top level requirement" ~~of 50 knots per hour speed~~. According to a summary of the tests, conducted in January and again in Mar, the ship exceeded 50 knots, handling high-speed, full-rudder maneuvers with ease. Another criticism called CONTOUR INTEGRAL's SFS-71 Air Search radar "redundant," claiming, "It is not needed as a back-up, nor is there a technical reason to have it on the cruiser." Vice Adm. Roland Coaster, Deputy CNO for Surface Warfare, responded by citing the system's "demonstrated value in air defense."

-more-

Figure 6-1.—Copy-edited story—Continued.

copy editor, using a soft, black lead pencil (the tool of the trade), would inscribe three horizontal lines under each letter that needs to be capitalized. The copy will then appear as follows:

mr. poindexter.

≡ ≡

When the copy is corrected, the copy editor's shorthand indicates that the final work should read as follows:

Mr. Poindexter.

Most of the copy-editing symbols described in figure 6-2 are standard to both the Navy and

commercial media. There will be only minor variations from one newspaper to another. You should learn these symbols and use them to make changes in your own copy and copy others submit to you.

APPLYING BASIC RULES

What follows are the basic rules you should remember when copy-editing stories:

- Use a soft, black lead pencil.
- Make corrections above or within the lines where mistakes occur.

CONTOUR INTEGRAL 3-3-3-3

In a report prepared earlier this year, the navy said, "The introduction of the ACUTE system represents a long-awaited and much-needed step in the development of ~~Naval~~ weapons systems. (CONTOUR INTEGRAL) will ~~bring~~^f assets and capabilities to any ~~Operational Environment~~ from surface action groups to high-threat ~~Carrier Battle Group Operations~~. The ~~ship~~^z will do these things in a proven hull design and with a smaller crew than any ship of comparable size and abilities. It is a ship and a weapon system ~~for~~^z the '90s and beyond."

-end-

Figure 6-1.—Copy-edited story—Continued.

- Place the necessary copy-editing symbols at their correct points of insertion.
- Write legibly. Your longhand corrections will not do any good if they cannot be understood.
- If you want to add a new paragraph to the story, do not write it out in longhand in the margin or on the back of the original story. Type it out and insert it when you are making your corrections.
- After you copyedit a story, you should have a finished product. Any obvious mistakes that slip

by will be attributed to the copy editor, not the writer.

COPY-EDITING ELEMENTS AND USAGE

LEARNING OBJECTIVE: *List the elements applicable to copy editing and identify their usage.*

As a Navy Journalist assigned copy-editing duties, you should always strive for accuracy, rather than speed. You might adopt the slogan, "All I miss, they will print."

SYMBOL MEANING	EDITED COPY	EFFECT
Capitalize	north island	North Island
Make lower case	the commander	the commander
Make caps and lower case	JOHN PAUL JONES	John Paul Jones
Insert letter	his stories	news stories
Change letter(s)	action photo	action photo
Delete letter, close up	typewriter	typewriter
Delete letter, leave space	petty officer	petty officer
Insert word	news photos	news and photos
Change word	record pictures	record pictures
Delete word, close up	news worthy	newsworthy
Delete word, leave space	the men	the men
Insert space	news photos	news photos
Close up	news paper	newspaper
Insert period	the end The	the end. The
Insert comma, colon, semicolon	three four and	three, four and
Insert hyphen	reenter	re-enter
Insert dash	fact for example	fact--for example

SYMBOL MEANING	EDITED COPY	EFFECT
Insert quotes, apostrophe	"We believe..."	"We believe..."
Insert exclamation point, question mark	Wow!	Wow!
Delete punctuation	white and blue	white and blue
Transpose letters	captain	captain
Transpose words	run fast	fast run
Transpose sentences, paragraphs	Apply same principle as above, or circle first item and draw arrow to desired position; note with 1.	
Abbreviate or spell out	Doctor Dr. ninety-two 92 more	Dr. Doctor 92 ninety-two
More of story to come		
End of story	-30-, -end- or -un-	
Not a new paragraph	battle. Sailors are	battle. Sailors are
New paragraph	battle. Sailors are	battle. Sailors are
Correct as written	Jane Austen	Jane Austen
Let it stand as before corrected	the F-14 Tomcat	the F-14 Tomcat
Center in column (heads and subheads)	Navy Day	Navy Day

Figure 6-2.—Copy-editing symbols.

Before you try filling the seat of copy editor, make sure you have a copy of the locally produced stylebook (see chapter 7 of the *JO 1 & NRTC*), as well as a copy of the latest version of *The Associated Press Stylebook and Libel Manual*. Both books are designed to standardize all newswriting and word usage for internal publications and for news releases to civilian media.

The copy-editing guidelines covered in this section are as follows:

- Style
- Editorializing
- Contradictions
- Incompleteness
- Names
- Numbers
- Spelling
- Punctuation
- Capitalization
- Abbreviations
- Military terms
- Religious terms

STYLE

Everyone in your office should be acquainted with the locally accepted stylebook, but it is up to the copy editor to catch any violations of good style.

It is annoying for an editor to pick up a story and find, for example, the word “avenue” spelled out one time, abbreviated as “ave.” a second time and written as “av.” a third time. An office that is careless or inconsistent about little things may eventually become careless or inconsistent about big things. Once a news medium loses respect for you, you might as well close shop. No newspaper will take the chance of publishing sloppy or carelessly prepared material.

Spelling, punctuation, capitalization, abbreviation and other mechanical aspects of grammar are details of writing that have a tremendously important impact on the clarity, readability and effectiveness of your copy. Once your office gets away from using a set stylebook, your news copy will slowly become a hodgepodge of inconsistencies.

EDITORIALIZING

Editorializing happens when a writer consciously or unconsciously expresses doubt, censure or praise in a news story. The only persons permitted to express an opinion in a straight news story are the persons in the story itself. Even then, the opinion quoted must be attributed to the person who gave it.

News stories should be written in the third person. The writer’s personal opinions should **never** be injected into a news story. Facts should be reported as they are found, without personal pronouns referring to the writer.

Editorials are articles in newspapers or magazines in which the views of their editors or those in control of the periodicals are intentionally presented. However, such articles are clearly identified and purposely set apart from the publication’s news and features.

The electronic media also offer editorial opinions, but they, too, take care to keep them separate from their regular newscasts.

Editorials require a very specialized style of writing—the fundamentals of which will not be covered in this NRTC. The focus of this section is the inclusion of personal opinions in your newswriting through carelessness or by design.

Consider the following examples of editorializing in straight news copy, then note the following suggestions offered to eliminate the implied opinions:

Poor: Lt Post is exceptionally well qualified for the position.

Improved: Lt Post, with a degree in law, has eight years of experience as a Navy legal officer.

Poor: An interesting program is planned for tonight at the Officer’s Club.

Improved: Here is tonight’s program at the Officer’s Club.

Poor: The punishment was unjust.

Improved: The U.S. Court of Military Appeals ruled that the punishment imposed by the court-martial was unjust.

CONTRADICTIONS

Sometimes, a writer makes contradictory remarks within a story without realizing it. When contradictions occur, the copy editor should delete them or rearrange

the facts more logically. Note the following four examples of typical contradictions:

Example #1

Robinson's keen sense of responsibility, devotion to duty and hard work, according to his commanding officer, finally paid off May 16 when he was advanced to Illustrator-Draftsman Third Class.

The 16-year veteran is assigned to the aircraft carrier...

If Robinson is such a responsible and devoted worker, why did it take him 16 years to make DM3? The reader will assume that Robinson is not too bright or that the Navy does not reward good men and women.

Example #2

A combat veteran of World War II, the Korean conflict and the Vietnam War, Capt. Garlin wears the American Defense Medal, the World War II Victory Medal, the Navy Occupation Service Medal, the National Defense Service Medal and the National Security Medal.

The captain may be a veteran of three wars, but his medals indicate he has seen no combat.

Example #3

Chief Clayborne began striking for Personnelman aboard the destroyer USS *Mitchel* in 1945.

The Personnelman rating was established in 1948, so Chief Clayborne could not have been a PN striker in 1945. He must have started out in another rating.

Example #4

Despite his 3-15 record and 7.89 earned run average, Bob Baker is considered to be a good pitcher.

Baker's pitching record and ERA speak for themselves. Classifying him as a "good pitcher" is both opinionated and contradictory. The writer would have to do a lot of explaining to justify this comment.

INCOMPLETENESS

As a JO, you should have "news sense"—a quality that tells you which facts to collect and use and which

facts to ignore. But if you do not have this ability or if you lose it momentarily, the copy editor must stop stories that are incomplete or inadequate and return them to you for amplification. This will save you the trouble of answering phone calls from news media representatives who want more detailed information.

Consider the following story, for example:

A Navy ground crewman was killed in an accident at U.S. Naval Air Station Bennington, the Navy announced today.

The man has been identified as George Pine of Chicago, Ill. He was directing a plane from the flight line onto a taxiway when the accident occurred. Bystanders reported that Pine walked into the blades of the spinning propeller. The pilot of the plane was attached to a squadron operating from the aircraft carrier USS *Loach*.

This story is compact and clearly written, but it will not satisfy the demands of the news media. Among other things, they will want to know the following:

- When did the accident occur? The Navy announced the story **today**, but nowhere does it say when the accident actually happened.
- Is there more detailed information on the victim? Readers will want to know his middle initial, age, rate, hometown address and data on his next of kin.
- How did the accident happen? The facts here are too generalized and vague.
- What was the plane doing at NAS Bennington when it was attached to the USS *Loach*?
- What is the name of the squadron, and where is the carrier operating?

A good copy editor should anticipate these questions. With a little copy editing, the story may look as follows:

- A Navy ground crewman was killed by the spinning blades of an aircraft propeller last night at U.S. Naval Air Station Bennington.
- The man was identified as Airman George A. Pine, 20, son of Mr. and Mrs. Andrew S. Pine of 8238 Earwig St., Chicago, Ill.

The accident occurred at 7:45 p.m., Japan time, while the crewman was directing an E-2

Hawkeye from the flight line onto a taxiway during a night exercise.

Pine noticed a flare pot near the plane's right landing gear and signaled the pilot to stop. As he attempted to move the object from the plane's path, he slipped in front of the aircraft and fell into its spinning propeller.

The plane and pilot are attached to Airborne Early Warning Squadron 779, normally based aboard the USS *Loach*. They were participating in night operations at NAS Bennington, while the carrier was docked at Yokosuka.

NAMES

"Names make news," but they also make headaches for the copy editor. Is the man's name **Haufman**, **Hoffman** or **Haufmann**? Did the writer accidentally leave the "h" off the name **Smit**, or is that how the name is actually spelled? How about the name **Frances Jones** in a news story? The writer implies it is a he, but males usually do not spell their names that way.

The names **Pat**, **Carol**, **Marion**, **Jean**, **Gale**, **Merle** and **Terry** can be either male or female. Therefore, the use of such a name without the knowledge of the person's gender could lead to some embarrassing situations. And what do you do when you run across a name like Stanley Wozniawirsbinski? You may not be able to pronounce it, but you had better make sure that it is spelled correctly.

To eliminate confusion for the typist or word processor when a name like Ppandrowske or Wozniawirsbinski is correct as written, simply draw a box around the odd but properly spelled name, as shown in figure 6-2.

NUMBERS

"Numbers do not lie," but a good copy editor frequently proves them wrong. Always be wary of numbers involving money, ages, dates, addresses, distance, performance records, statistical data and other compilations. If a number looks questionable, always refer it to the writer for verification.

A BM1 may be only 23 years old, but most likely he is 32. A seaman whose age is listed as 42 may really be 24. The JO who wrote the story may have hit the wrong keys on the keyboard. Another story says that

ET1 Jack Kelly was married four years ago. However, his children are mentioned and their ages are listed as 7 and 9. Readers will want to know why.

The beginning of a story may say that seven men were killed or injured in a plane crash, yet the casualty list may contain the names of only six. Readers will want to know what happened to the seventh name. A story may announce the opening of a new commissary on Monday, January 18. A check with your calendar, however, indicates that Monday, January 18 is Martin Luther King Jr. Day, and commissaries are not normally open on federal holidays.

Watch for the logic in statistical data. Double-check league standings to be sure the numbers of wins and losses balance. Do not use postal box numbers for addresses. People receive their mail in boxes. However, they do not live in them.

In general, spell out all numbers from one to nine, and use numerals for 10 and above. Numerals are used exclusively in tabular and statistical matters, records, election returns, times, speeds, latitude and longitude, temperatures, highways, distances, dimensions, heights, ages, ratios, proportions, military units and dates. Fourth of July and July Fourth are exceptions as are Fifth Avenue, Big Ten and Dartmouth Eleven.

Times are 6:30 p.m. Monday or 6:30 Monday evening. **Never** use 6:30 p.m. Monday evening. Evening and p.m. are synonymous.

In a series of numbers, apply the appropriate guidelines: There are three 10-room houses and 40 four-room houses in the development. He has six suits, 14 pairs of shoes, but only one tie.

Casual numbers such as in the following examples are spelled out: A thousand times, no! Gay Nineties. Wouldn't touch it with a ten-foot-pole. However, numerals are used when using an exact measure as in the following example: The flag hung from a 10-foot pole.

Spell out fractions when used alone as in this example: Three-quarters of a mile. For amounts more than one, use numerals as follows: Her shoe size is 6 1/2. Convert to decimals whenever practical.

For further information, consult the latest edition of *The Associated Press Stylebook and Libel Manual*.

SPELLING

If you think you know how to spell well enough to get along without a dictionary, try spelling the

following 10 words (chances are, you will misspell a few of them):

- inoculate or inoculate
- embarrass or embarrass
- supercede or supersede
- larynx or larynx
- interfered or interfered
- indispensable or indispensable
- liaison or liaison
- diphtheria or diphtheria
- harass or harass
- accommodate or accommodate

If you selected inoculate, embarrass, supersede, larynx, interfered, indispensable, liaison, diphtheria, harass and accommodate as the correct spelling, throw away your dictionary. But, if you misspelled one or more words start using your dictionary regularly. These are only 10 examples of troublesome words in the English language. Of course, there are thousands more. Undoubtedly, you have your favorites when it comes to misspelling words. So, compile your own list of frequently misspelled words and start eliminating them from your list.

In mastering words, there are certain basic rules for spelling that will help you. Unfortunately, for every spelling rule there are numerous exceptions. Some spelling rules have so many exceptions that they can just barely be classified as rules. Your computer has a dictionary and thesaurus. Do not tell it to accept an incorrectly spelled word as correctly spelled. The point to remember is that your printed dictionary is the final authority.

The most useful of the spelling rules and some examples and exceptions are listed below:

1. When a one-syllable word or a longer word that keeps the accent on the last syllable ends in a single consonant preceded by a single vowel, double the final consonant before adding a suffix beginning with a vowel.

Examples:

- a. Clan, clannish
- b. Plan, planned, planning
- c. Control, controlled

- d. Refer, referring—but, reference (because the accent has shifted away from the last syllable of the basic word)
- e. Occur, occurred, occurrence

2. Words ending in a silent *e* generally retain this *e* before a suffix beginning with a consonant. When the suffix begins with a vowel, the silent *e* is usually dropped.

Examples:

- a. Excite, excitement; late, lately
- b. Tide, tidal; shape, shaping

3. When the final sound of the word is a soft *c*, *g* or *ng*, the final *e* is retained before some suffixes beginning with vowels.

Examples:

- a. Peace, peaceable
- b. Advantage, advantageous; courage, courageous
- c. Change, changeable, but changing

4. Words ending in *y* preceded by a consonant usually change the *y* to *i* before a suffix. Words ending in *y* preceded by a vowel do not change the *y* before a suffix.

Examples:

- a. Icy, iciest; mercy, merciless; modify, modifies, modifiable; pity, pitiable, pitiful
- b. Obey, obeying; joy, joyful, joyous

5. When the sound is *c*, remember the rhyme, “*i* before *e* except after *c* ...”

Examples:

- a. Believe, belief, relieve, relief
- b. Receive, conceive, perceive, conceit

Exceptions:

Weird, seize, neither, leisure, financier, inveigle.

- 6. The previous rhyme ends “... or when sounded as *a* as in neighbor or weigh.”
- 7. Verbs ending in *ie* generally change *ie* to *y* before *ing*.

Examples:

Die, dying; lie, lying

Learning to spell is more a matter of establishing a correct image of each word than of applying rules. Usually the image is a visual one. Knowing the correct pronunciation often helps, but in the English language we have many words for which pronunciation is no guide to spelling (e.g., duty, beauty, grew, blue), so we must rely on the way the word looks. While you are looking up an unfamiliar word, make an effort to fix its spelling in your mind along with the meaning and pronunciation.

PUNCTUATION

Punctuation in writing serves the same purpose as voice inflection in speaking. Proper phrasing avoids ambiguity, ensures clarity and lessens the need for punctuation.

Period

The period (.) serves the following functions as shown in each example:

- To mark the end of a sentence

Example: Close the door.

- To accentuate most abbreviations

Examples: U.S., c.o.d.

- To separate integral and decimal numerals

Examples: 3.75 percent, \$3.75, 3.75 meters

Ellipsis

The ellipsis (...), three periods and two spaces, is used for the following functions as shown in each example:

- To indicate omitted material

Example: "I pledge allegiance to the flag ... and to the Republic. ...")

Comma

The comma (,) serves the following functions as shown in each example:

- To separate various elements within a sentence and to indicate a slight pause

Examples: When lightning struck, Bob Smith fainted. When lightning struck Bob, Smith fainted.

- To separate clauses

Example: They fought the battle, but no one won.

- To separate a series

Example: Neither snow, rain, nor heat ...

- To set off attributions

Example: "The work," he said, "was exacting and satisfying."

- To set off apposition or contrast

Example: Wilson, the favorite, won handily.

As used in the following examples, the comma is omitted before Roman numerals, Jr., Sr., the ampersand (&), the dash, in street addresses and Social Security numbers.

Examples: Louis XIV, Joe James Jr., Smith & Co., 54321 Pine St., 123-45-6789.

Newspaper usage has, in most cases, eliminated the comma before "and" and "or" in a series, but a comma is still required before "and," "or" and other conjunctions in compound sentences. Note the following example:

Example: Fish abounded in the lake, and the shore was lined with deer.

Semicolon

As used in the examples that follow, the semicolon (;) separates phrases containing commas to avoid confusion, separates statements of contrast and statements closely related.

Examples: The party consisted of E. E. Wright; R. J. Kelly, his secretary; Mrs. Jordan; Martha Bowen, her nurse; and three accountants. (Without the semicolons, that could read as nine persons.) The draperies, which were ornate, displeased me; the walls, light blue, were pleasing. Yes; that is right.

Colon

As used in the following examples, the colon (:) precedes the final clause and summarizes previous material; introduces listings, statements and texts; marks discontinuity; and takes the place of an implied "for instance."

Examples: States and funds allotted were as follows: Alabama -\$6,000, Arizona- \$14,000. The question came up: What does he want to do?

The colon also is used in the following manners and examples:

- In clock time

Examples: 9:20 p.m., 10:30 a.m.

- In Biblical and legal citations

Examples: Matt. 2:14, Missouri Statutes 3:234-432

Question Mark

The question mark (?) follows a direct question. Occasionally, it is used to indicate uncertainty, as with some dates or identifications. In the latter use, it is enclosed in parentheses. Note the following examples:

Examples: What happened to Dean? Columbus, an Italian (?) sailing for the Spanish crown, discovered America ...

Exclamation Point

The exclamation point (!) is used to indicate surprise, appeal, incredulity or other strong emotion as in the following examples:

Examples: You are wonderful! What! He yelled, "Help!"

Apostrophe

The apostrophe (') indicates the possessive case of nouns, omission of figures and contractions. Usually, the possessive of a singular noun not ending in "s" is formed by adding the apostrophe and the "s" as in the example that follows:

Example: The boy's ball, but the boys' bats.

The apostrophe is used in the following instances and examples:

- After plural possessives

Examples: the girls' coats; the marines' rifles.

- In contractions

Examples: I've, isn't, don't.

- In omission of figures

Examples: '90s, Class of '22.

The "s" is omitted and only the apostrophe used in "for conscience's sake" or in a sibilant double or triple "s" as Moses' tablet.

As in the following examples, the apostrophe is **not** used to form plurals unless it is in the context of the exception shown:

Examples: MiGs, P-3s, B-52s, ABCs.

Exception: When a single letter is made plural, as in "mind one's p's and q's," the apostrophe is required.

Quotation Marks

Quotation marks (" ") enclose direct quotations, phrases in ironical uses, slang expressions, misnomers and full titles of books, plays, poems, songs, lectures, speeches, hymns, movies, television and so forth.

As in the next example, use quotation marks around nicknames when a person's full name is used.

Example: Paul "Bear" Bryant.

Note the following examples in which the comma and period are placed inside the quotation marks. Other punctuation is placed inside quotation marks only when it is part of the matter quoted.

Examples: Why call it a "gentlemen's agreement"? He asked, "Is the interview completed?"

Parentheses

Parentheses () serve the following functions as shown in each example:

- To set off material not intended to be part of the main statement or that is not a grammatical element of the sentence, yet important enough to be included

Examples: It is not customary (at least in the areas mentioned) to stand at attention. "That proposal," he said, "and one by (Prime Minister John) Major are being studied."

- To facilitate further identification that is not part of the official name

Example: The Springfield (Virginia) Historical Society.

- To set off letters or figures in a series

Examples: The order of importance will be (a) general acceptance, (b) costs and (c) opposition. The water is (1) tepid, (2) muddy from silt and (3) unpalatable.

Dash

As shown in each example, the em dash (—) is used in the following cases:

- To indicate a sudden change and interjection

Examples: The commander—do you know who I mean?—approved it. If that man gains control—God forbid —our troubles will have just started.

- After a dateline and before the first word of a story

Example: NEW YORK—Five people were injured. ...

Note that a dash consists of two strokes of the hyphen (or minus sign) key on your computer keyboard.

Hyphen

The hyphen (-) is used to separate compound words, figures, abbreviations and figures, double vowels in some cases and to divide a word at the end of a line.

The general rule for hyphens is that “like” characters take the hyphen; “unlike” characters do not. Note the following examples:

Examples: Secretary-Treasurer (compound word); 20-20 vision (figures); bell-like (use a hyphen to avoid tripling a consonant).

Other uses of the hyphen and examples are as follows:

- Adjectival use of hyphens must be clear.

Examples: The 6-foot man eating shark was killed (the man was). The 6-foot man-eating shark was killed (the shark was).

- Ordinarily, in prefixes ending in vowels and followed by the same vowel, the hyphen is used.

Example: pre-eminent. (Check dictionary for exceptions such as cooperate, coordinate, etc.)

- The hyphen also serves to distinguish between meanings of similarly spelled words.

Example: recover (from illness), re-cover (couch).

- The hyphen separates a prefix from a proper noun.

Examples: un-American, pre-Christian era.

Do not use a hyphen between “vice” and “president” or other such titles, or with adverbs ending in “ly.” Note the following examples:

Examples: badly damaged car, fully informed public, newly elected official.

CAPITALIZATION

In newswriting, capitalization is correct in the following cases, examples and exceptions:

- The first word of a sentence

Example: Good grammar is essential.

- Titles and ranks (rates) followed by a proper noun, but lowercase titles standing alone or following a name

Example: Secretary of State C. R. Dryden, but C. R. Dryden, secretary of state.

Exception: The President of the United States is always capitalized.

- Pope and the titles of foreign religious leaders, when used as a formal title before a name, but lowercase when titles stand alone or follow names

Exception: Dalai Lama is capitalized in all usages, since that title is used instead of the name of the person holding that office.

- Months and days, but not seasons

Example: Last summer our vacation began on the first Thursday in August.

- All holidays, historic dates, religious holidays, special events, military exercises, hurricanes and typhoons

Examples: Christmas, Father’s Day, Washington’s Birthday, National Safety Week, Operation Desert Storm, Typhoon Gay, Hurricane Andrew.

- All proper nouns or names

Examples: Marty Martin, Bangkok, Hudson River.

- All names of countries and their languages, unions, republics and colonies

Examples: He learned to speak French in France. India is a former British colony. Other examples are Union of South Africa and Republic of Korea.

- Specific regions

Examples: Middle East, Midwest, Southern California, Panhandle, Arctic Circle but lowercase antarctic or arctic in reference (arctic wind).

- Appellations

Examples: Buckeye State, Leatherneck, Project Apollo.

- All decorations and awards

Examples: He was awarded the Medal of Honor. His father received the Nobel Peace Prize. She was awarded the Navy Marine Corps Achievement Medal for professional achievement.

- All nouns referring to the deity of all monotheistic religions

Examples: God the Father, Holy Ghost. Also capitalize Satan and Hades, but not devil or hell. Lowercase gods and goddesses in reference to the deities of polytheistic religions.

- Names of races

Examples: Indian, Chinese, Caucasian. Lowercase yellow, white, black. (Identification by race should be made only when it is pertinent.)

- The first letter of each word, except articles, conjunctions and short prepositions that are not the first word, in titles of books, plays, hymns, poems and songs

Examples: “All the Ships at Sea,” “Damn Yankees,” “O” Come All Ye Faithful.”

- U.S. government and state government agencies, branches, committees and departments when the full name is used

Examples: Federal Communications Commission, Interstate Commerce Commission. In addition, always capitalize U.S. Congress and U.S. or state Senate, House and Legislature when referring to a specific body.

Examples: the Florida Senate, the Texas Legislature and the Senate, when clear reference is made; the word government, when used alone or with an adjective, is lowercased.

Example: She works for the government.

- Ideological or political areas

Example: East-West relations are at a stalemate. Use lowercase when referring to direction. **Example:** Some say the western part of Florida has nicer beaches than the eastern part.

- Names of organizations, expositions and so forth

Example: The Boy Scouts will visit the World’s Fair. Lowercase “scout” and “fair” when they are standing alone.

ABBREVIATIONS

To abbreviate is to make a word or phrase shorter by leaving out or substituting letters. Some military and civilian terms are so long that abbreviation is almost a must. However, always spell out the name of organizations or groups on its first use. If a name does not have a commonly known abbreviation, the abbreviation should be parenthesized after the first spelling. Thereafter, you may use just the abbreviation as in this example: The guidelines of the Civilian Health and Medical Program of the Uniformed Services (CHAMPUS) have changed. ...

The abbreviations that follow and those used throughout this training manual are basically those standardized for civilian and military newswriting by The Associated Press.

In newswriting, abbreviate the following and note the examples of each:

- Time zones, aircraft and ship designations, distress calls, military terms and so forth

Examples: EDT, MiG-17, SOS (but May Day), USS *John F. Kennedy*, SS *Virginia*.

- Business firms

Examples: Warner Bros., Brown Implement Co., Amalgamated Leather, Ltd. If “and” is in the firm name, use the ampersand (&).

Examples: Sims & Sons, AT&T.

- Street, avenue, boulevard and terrace in addresses when using a numerical prefix, but not point, port, circle, plaza, place, drive, oval, road or lane

Examples: 30 E. 28th St. (single “E” with period), 16 Quentin Ave. NW (no periods in “NW”), 27 Sunset Blvd., but Main Street, Fifth Avenue and so forth

- Versus to read vs. (with period)
Example: The case of Johns vs. New York.
- Most states when used with cities, towns, bases, Indian agencies and national parks
- **Examples:**

Ala.	Ill.	Miss.	N.C.	Vt.
Ariz.	Ind.	Mo.	N.D.	Va.
Ark.	Kan.	Mont.	Okla.	Wash.
Calif.	Ky.	Neb.	Ore.	W.Va.
Colo.	La.	Nev.	Pa.	Wis.
Conn.	Md.	N.H.	R.I.	Wyo.
Del.	Mass.	N.J.	S.C.	
Fla.	Mich.	N.M.	S.D.	
Ga.	Minn.	N.Y.	Tenn.	

Do not abbreviate Alaska, Hawaii, Idaho, Iowa, Maine, Ohio, Texas or Utah. Never abbreviate the name of states when they are used alone.

- Names of provinces and territories are set off from community names by commas, just as the names of U.S. states are set off from city names

Example: They went to Halifax, Nova Scotia, on their vacation.

- United Nations and United States when used as adjectives, but spell them out when used as nouns. In texts or direct quotations, U.S.A., U.S. and U.N. may be used as nouns

Examples: He is a former U.S. Olympic champion. She is a member of the U.N. Educational, Scientific and Cultural Organization (UNESCO). While visiting the United States, she toured the United Nations Building in New York. “When last I was in the U.S.A., the U.N. was in its infancy.”

- All religious, fraternal, scholastic or honorary degrees and so forth, but lowercase when spelled out

Examples: J. J. Jones earned his bachelor of science degree at Princeton. J. J. Jones, Ph.D., will be guest speaker at 2 p.m. tomorrow.

- Titles (and capitalize) Mr., Mrs., Mlle., Dr., Prof., Sen., Rep., Dist. Atty., Gov., Lt. Gov., Gen., Supt. and so forth, when they appear before names but not after

Examples: He introduced Lt. Gov. J. F. Petty. J. F. Petty, the lieutenant governor, will arrive at 10:15 a.m. In first and subsequent references and in group names, use “Miss” before the name of an unmarried woman and “Mrs.” before the name of a married woman, or “Ms.” if preferred by the individual. **Example:** Those attending were, Miss Alice Jones, Mrs. Helen Jones and Ms. Gladys Jones.

- Months when used with dates, but spell out otherwise

Example: The battle started Oct. 10, 1967, and ended in January 1968. Abbreviations for months are Jan., Feb., Aug., Sept., Oct., Nov., Dec. Do not abbreviate March, April, May, June or July **except** when used in tabular or financial routine; then use Mar., Apr., Jun. and Jul. and spell out May.

- Mount when referring to a mountain but spell out when referring to a city

Examples: Mt. Everest, Mount Vernon, N.Y.

- Fort when it is an Army post, but spell out when it is a city

Examples: Ft. Sill, Fort Lauderdale, Fla.

In the following cases, **do not** abbreviate and note the accompanying examples and exception:

- Days of the week except in tabular or financial matters. In these cases use Mon., Tues., Wed., Thurs., Fri., Sat., Sun.

- First names unless the person does

Examples: William, not Wm.; Frederick, not Fred; Benjamin, not Benj.

- Measurements—the one exception to this rule is the word millimeter, which may be abbreviated as mm (no space) when used with a numeral in first or subsequent references to film or weapons. Miles an hour and miles per hour are abbreviated in subsequent reference only and must have a numerical prefix

Examples: He used a 35mm camera. She was driving 60 miles an (per) hour but slowed down to 30 mph in the housing area.

- Port, association, point, detective, department, deputy, commandant, commodore, field marshal, secretary-general, secretary or treasurer

- Christmas or use Xmas
- Cities

Exception: Saint is abbreviated to St., when it is part of a city name. **Example:** St. Augustine, Fla.

These well-known cities are used without a state suffix:

Atlanta	Houston	Philadelphia
Baltimore	Indianapolis	Phoenix
Boston	Las Vegas	Pittsburgh
Chicago	Los Angeles	St. Louis
Cincinnati	Miami	Salt Lake City
Cleveland	Milwaukee	San Antonio
Dallas	Minneapolis	San Diego
Denver	New Orleans	San Francisco
Detroit	New York	Seattle
Honolulu	Oklahoma City	Washington

MILITARY TERMS

One of the chief complaints of civilian editors concerning military journalism is the excessive use of abbreviations for titles and organizations. In the majority of cases, most people within a particular service will know most of its standard abbreviations. However, many will not know them all, particularly family members, visitors and new service personnel.

Titles and organizational designations should always be spelled out in the first reference —except those that are so well known that it would be a definite waste of space.

All foreign services should be lowercased and spelled out; for example, French army. Military jargon and colloquial expressions should be avoided unless they are used in proper context or direct quotes. When possible, eliminate abbreviated terms to differentiate between a professionally written news article and a set of travel orders. Some examples of military abbreviations that you should not use in news stories include the following:

- TAD (temporary additional duty)
- R&R (rest and recreation)
- RON (remain overnight)
- OOD (officer of the day (deck))
- PCS (permanent change of station)

When you refer to members of a particular service, use the following collective terms:

- Soldier (a member of the U.S. Army)
- Sailor (U.S. Navy)
- Marine (U.S. Marine Corps)
- Airman (U.S. Air Force)
- Coast Guardsman (U.S. Coast Guard)
- Guardsman (Army or Air National Guard)

For military rank and title abbreviations, by service, consult the latest edition of *The Associated Press Stylebook and Libel Manual*.

Thousands of doctors, nurses, veterinarians, dentists, chaplains and lawyers serve the military in their respective professional capacities. As such, they should be identified in news stories by their profession. This identification should be made in the first reference. Note the following examples:

Examples: Capt (Dr.) Joe Johns of the Portsmouth Naval Hospital conducted ... Cmdr. Edna Knox, Navy Nurse Corps, told medical authorities ... Maj. (Dr.) Larry Riley, a veterinarian, stressed the importance ... Navy Chaplain (Cmdr.) John Frisby will preside over ... (**Note:** A chaplain's rank is enclosed in parentheses. In the previous example, subsequent references would be Chaplain Frisby.)

Lawyers are not identified by profession in the military service per se. However, in all possible cases, they should be referred to in relation to their role in the story. Consider the following example:

Example: Coast Guard Lt. Henry Smith, the defense attorney (trial lawyer, staff judge advocate, etc.), a member of the Maryland Bar Association, moved for a dismissal of the charges.

In many cases, news stories require the use of a person's service in addition to name and rank, particularly in joint maneuvers. When this occurs, place the service identifier before the rank and name as in the following examples:

Examples: Navy Capt Rob Rogers; Coast Guard Lt Jim King; Air Force Maj. Richard Johnson. (The "U.S." before Army, Navy, Air Force, Coast Guard or Marine Corps is optional unless tied in with foreign dissemination.)

Women, military as well as civilian, should receive the same treatment as men in all areas of news coverage. Never use sexist references, demeaning

stereotypes and condescending phrases in reference to women. The same standards for men and women should be used in deciding whether to include specific mention of personal appearance, physical description or marital and family situation.

As in the following examples, aircraft, ships and other military equipment should be identified by popular name and model designation.

Examples: The Air Force Lockheed C-141 *Starlifter* flew. ... Each soldier carried an M-79 grenade launcher. ... The aircraft carrier USS *Lexington* (AVT 16), “Lady Lex,” was opened as a floating museum. ...

RELIGIOUS TERMS

There is only one way to refer to confessions of faith, their members and officials—the correct way. While general usage and correct titles of some of the faiths are listed below, many are not. When in doubt, consult your chaplain’s office. Members of communions of the National Council of the Churches of Christ in the United States of America (official title, which may be shortened to National Council of Churches) are as follows:

African Methodist Episcopal Church
African Methodist Episcopal Zion Church
American Baptist Convention
American Lutheran Church
Antiochian Orthodox Christian Archdiocese of North America
Armenian Church of America
Christian Church (Disciples of Christ)
Christian Church of North America, General Council
Christian Methodist Episcopal Church
Friends United Meeting (Five Years Meeting)
Greek Orthodox Archdiocese of North and South America
Hungarian Reformed Church in America
Moravian Church
National Baptist Convention of America
National Baptist Convention U.S.A. Inc.
Orthodox Church in America
Polish National Catholic Church of America

Presbyterian Church in the U.S.
Progressive National Baptist Convention Inc.
Protestant Episcopal Church
Romanian Orthodox Episcopate of America
Seventh-Day Adventist
Southern Baptist Convention
Ukrainian Orthodox Church of the U.S.A.
United Church of Christ
Lutheran Church in America
United Methodist Church
United Presbyterian Church in the U.S.A.

Other communions include the following:

Churches of Christ
Church of Christ, Scientist
Church of Jesus Christ of Latter-day Saints
Jehovah’s Witnesses
Religious Society of Friends
Roman Catholic Church
Unitarian Universalist Association

Jewish groups include the following:

Union of American Hebrew Congregations
Union of Orthodox Jewish Congregations in America
United Synagogues of America

Rabbinical groups include the following:

Central Conference of American Rabbis
Rabbinical Assembly of America
Rabbinical Council of America
Union of Orthodox Rabbis of the United States and Canada

The Synagogue Council of America represents both the congregational and rabbinical groups of Orthodox, Reform and Conservative Judaism. Their places of worship are temples or synagogues. The generic term is Jewish house of worship.

In general written reference to a member of the clergy, use the following: the Rev. John Smith, or the Rev. Mr. Smith. Do not use Rev. without Mr., Miss, Mrs., Ms., a first name or initials. A chaplain is

referred to as a chaplain with his rank following in parentheses on the first usage. Note the following examples of the correct use of titles:

Example: Chaplain (Lt.) John Smith ... then, Chaplain Smith.

The title “Dr.” is used only when the doctorate degree is actually held.

Examples: the Rev. Dr. Betty Johns; Dr. Johns; The Rev. Betty Johns, D.D. (Doctor of Divinity).

Roman Catholic usage: the Rev. Joe Jones; Father Jones; the Most Rev. Joe Jones, bishop of the Denver Diocese; Bishop Jones; Francis Cardinal Jones; Cardinal Jones.

A nun is addressed as “sister,” which is capitalized in all references before her name. When a surname is given in the first reference, use both given name and surname (Sister Mary Elizabeth Smith); and in subsequent references, use only the surname (Sister Smith). When the surname is not provided, the name is the same in all references (Sister Mary Elizabeth). Do not abbreviate the word “sister.”

Episcopal usage: A priest is referred to as the Rev. John Jones or the Rev. Mr. Jones. A dean is the Very Rev. John Jones, the Rev. Jones, Mr. Jones or Dean Jones. A bishop is the Rt. Rev. John Jones, the Rt. Rev. Mr., or Bishop Jones. A member of the Episcopal Church is an Episcopalian.

Jewish usage: Rabbi John Goldstein, Rabbi Goldstein, Dr. Goldstein (where degree is held). Cantor John Goldstein, Cantor Goldstein. Never identify a rabbi as Reverend Doctor.

Christian Science usage: Practitioner, Lecturer, Reader Joe Jones. Never “reverend” in any form. Reader Jones of the First Church. The Mother Church (Boston church only).

Methodist usage: Pastor, minister, preacher, bishop. Use of the Rev. Mr. Jones is acceptable.

Lutheran usage: In the United States—Pastor John Jones, Pastor Jones, Mr. Jones. Scandinavian Lutheran usage follows the Episcopal forms.

Latter-Day Saints (Mormon) usage: President John Jones, President Jones, Elder Jones, Presiding Bishop John Jones, Bishop Jones, Presiding John Jones of the Presiding Bishopric. Members of the church are Mormons.

It is incorrect to apply the word church to any Baptist unit except the local church. The organization of Southern Baptists is the Southern Baptist Convention.

The American Lutheran Church, the Evangelical Lutheran Church and the United Evangelical Lutheran Church merged in 1960 into the American Lutheran Church with headquarters in Minneapolis, Minn.

Unitarian and Universalist denominations are known as the Unitarian Universalist Association.

There are other faiths that have mosques, dioceses, archdioceses, areas, synods, presbyteries, and so forth. If in doubt, you should consult your chaplain’s office for the accurate designations and changes.

COMMON SENTENCE STRUCTURE ERRORS

LEARNING OBJECTIVE: *Recognize the common errors in sentence structure.*

The sections on spelling, capitalization and punctuation have all contributed to the construction of good sentences. However, to be effective, sentences must be grammatically correct. In addition, they should be well-chosen and effectively combined with a goal of clarity, emphasis and interest. These goals are often thrown off target by any one of a variety of common errors in sentence structure.

SENTENCE FRAGMENTS

In terms of grammar, writers are frequently at fault for writing incomplete sentences. For a sentence to express a complete thought, it must contain two necessary parts—a subject and a predicate or verb. It is possible, of course, for the subject to be understood, rather than stated, but you should be sure in such cases that it is clearly implied.

Some examples of incomplete sentences include the following:

- The sightseeing tour, which was arranged for the liberty party. (There is no main verb. The relative clause has a verb, “was arranged,” but what appears to have been intended as a statement with “sightseeing tour” as subject has not been completed.)
- A tall, thin man with owlsh spectacles and a bald head. (The verb is omitted.)

- Floated toward the beaches. (Here the subject is omitted. What floated?)
- Just as the searchlight swept across the harbor. (This tells when something happened, but the main statement is still incomplete.)
- Bailey, the new striker, looking as if he would burst with pride. (There are modifiers here for the subject, “Bailey,” but no main statement about that individual.)

Often an incomplete sentence results from the writer’s failure to recognize that a modifying phrase or clause is really part of the preceding sentence. For instance, a comma should be used instead of the first period in the following example:

- The cruiser was headed for the canal zone.
Steaming eastward through the Caribbean.

The result in this case is one complete sentence instead of a sentence followed by a fragment.

You should not be misled by the fact that some writers deliberately construct incomplete sentences at times. As the late Emily Post once said about etiquette: “Well-bred persons sometimes break some of the rules; but to break them and get away with it, you first have to know them.”

It is true that fractured sentences may occasionally produce the desired effect, but be sure you know why they are being used and that they are suitable to what is being written. Many regard a sentence that begins with “but,” or another connective, as incorrect, largely because the connective standing first seems to indicate a fragment. In this instance, the rule may be ignored occasionally, if by doing so you achieve a more effective statement.

RUN-ON SENTENCES

Another common error in sentence structure is the punctuation of two or more sentences as if they were one. This usually occurs with sentences that are closely related in thought. Note the following examples:

Poor: The ship held its first swim call, the water was 4 miles deep.

Improved: The ship held its first swim call.
The water was 4 miles deep.

Often a run-on sentence is the result not only of faulty punctuation, but of the writer’s failure to think the construction through and recognize the

relationships of the various ideas. Consider the following examples:

Poor: Detailed decontamination is a lengthy process, it is usually carried on at a home base or rear area.

Improved: Detailed decontamination is a lengthy process, usually carried on at a home base or rear area.

Poor: An emergency tourniquet can be made from something like a neckerchief, it is wrapped once around the limb and tied in an overhand knot.

Improved: To apply an emergency tourniquet made from something like a neckerchief, wrap the material once around the limb and tie an overhand knot.

DANGLING MODIFIERS

A writer’s misplacement of a modifier can confuse the meaning of the sentence, often with ludicrous results. Modifiers should be positioned close to the words they modify; otherwise, they may seem to modify something else. Haste, carelessness or lack of understanding of grammar may cause a writer to use a construction without thinking exactly what a particular word is supposed to modify. This kind of error is fairly common in using participles with other adjectives or with adverbial modifiers, as in the following examples:

Dangling Participle: Returning to the ship, the package was found on his bunk.

Improved: Returning to the ship, he found the package on his bunk. (It was he who returned to the ship, not the package.)

Dangling Participle: Entering the halon-flooded compartment, the gas overcame him.

Improved: Entering the halon-flooded compartment, he was overcome by the gas.

Dangling Participle: Running rapidly out from the windlass, he caught his foot in the anchor chain.

Improved: He caught his foot in the anchor chain, as it ran rapidly out from the windlass.

Misplaced Prepositional Phrase: At the age of two his father died.

Improved: He was two years old when his father died.

Misplaced Prepositional Phrase: Baker saw the driver of the car that had hit him in the theater.

Improved: In the theater, Baker saw the driver of the car that had hit him.

Misplaced Relative Clause: The chief mess management specialist discovered that old baking powder had been used in the biscuits, which caused all the trouble.

Improved: The chief mess management specialist discovered that the trouble with the biscuits was the use of old baking powder.

A frequently misplaced word is “only.” By moving this one word around in a sentence, you can change the meaning entirely. Study the following example:

- Only he could read the strange dialect.
- (Nobody else could.)
- He could only read the strange dialect.
- (He could not write or speak it.)
- He could read only the strange dialect.
- (He could read nothing else.)
- He could read the only strange dialect.
- (Only one dialect was strange, and he could read it.)

MISPLACED CORRELATIVE CONJUNCTIONS

Correlative conjunctions, (such as **not only—but also** and **either—or**) are often misplaced. Their correct position is just ahead of the words or groups of words they connect. Consider the following examples:

Misplaced: The Navy letter form **not only** omits the salutation **but also** the complimentary close. (The words that should be connected are “salutation” and “complimentary close”.)

Correct: The Navy letter form omits **not only** the salutation **but also** the complimentary close.

Misplaced: **Either** secure lines to the arresting hook **or** the hoisting sling. (As this sentence stands, the words that should be connected are

“arresting hook” and “hoisting sling.” The sentence will be better, however, if two complete prepositional phrases are used instead.)

Correct: Secure lines **either** to the arresting hook **or** to the hoisting sling.

Other frequently used correlative conjunctions are “both—and,” “neither—nor” and “whether—or.”

SPLIT INFINITIVES

Splitting an infinitive means placing one or more modifiers between the “to” and the verb form. You will hear people say that a split infinitive is no longer regarded as incorrect, but that is only a partial truth. Some writers consider that splitting an infinitive is desirable at times for the sake of emphasis; for example, “To **deliberately** disobey an order is a serious offense.” Even this sentence will grate on some ears, and generally, it is better for you to keep the adverb outside the infinitive construction. That is especially true when you have more than one adverb or a phrase.

Awkward Split: The only way for a person to win against a fire is **to** regularly and thoroughly **practice** the rules of fire prevention.

Better: The only way to win against a fire is **to practice** rules of fire prevention regularly and thoroughly.

ERRORS IN AGREEMENT

You probably have no trouble, most of the time, with agreement of verb and subject. You are not tempted to write: “The propellers was damaged.” But how about, “The propeller and shaft was damaged”? Wrong, to be sure, but it is an easy mistake to make when you are thinking of the two parts of a compound subject as belonging together. It should, of course, read “The propeller and shaft **were** damaged.”

In a compound subject with “or” or “nor” as a connective, the verb should agree in number with the **last** noun in the subject.

Incorrect: Neither the propellers nor the rudder **are** damaged.

Correct: Neither the propellers nor the rudder **is** damaged.

When a parenthetical expression beginning with words such as “together with,” “with” or “including”

comes between the subject and the verb, there is a temptation to make the verb plural as if the subject were compound. Consider the following example:

Incorrect: One mast, together with a spar running athwartship, **are** used for flags.

Correct: One mast, together with a spar running athwartship, **is** used for flags.

Disagreement between subject and verb sometimes occurs because, in a complicated sentence, a nearby noun is mistaken for the subject. This is the case in the following example, in which the plural nouns “officers” and “commands” seem to have confused the writer. The subject of the sentence, however, is “duty.”

Incorrect: The primary duty of such staff dental officers serving in these commands **are** very similar to those of a district dental officer.

Correct: The primary duty of such staff dental officers serving in these commands **is** very similar to that of a district dental officer.

Correct: The primary duties of such staff dental officers serving in these commands **are** very similar to those of a district dental officer.

GERUNDS

A gerund is a verb (verb form) used like a noun. For example: **Running** is good exercise. A gerund retains some of its verb qualities, however, such as taking a subject or object, or being modified by adverbs. Only one of these verb qualities—taking a subject—differs from what would be used with the same verb if complete. The subject of a gerund is in the possessive case instead of the nominative. For example: Had you heard about his **passing** the test?

“Passing” is a gerund with “his” as the subject and “test” as the object. The complete phrase is used here as the object of the preposition “about.”

ERROR IN NOUN CLAUSES

The pronoun that introduces a noun clause is sometimes given the wrong case because of the writer’s failure to recognize the structure of the sentence. The case of any pronoun is determined by its use in the clause of which it is a part. Note the following examples:

Incorrect: The award will go to **whomever** submits the best entry.

Correct: The award will go to **whoever** submits the best entry.

“Whoever submits the best entry” is a noun clause. The whole clause is used as the object of the preposition “to.” “Whoever” is the subject of the clause and therefore nominative.

COPY-EDITING MESSAGE RELEASES AND NEWSWIRE COPY

LEARNING OBJECTIVE: *Identify the methods used in copy-editing message releases and newswire copy.*

A **message** is an official communication in brief form transmitted by rapid means such as telegraph, radio, flashing light, flaghoist or semaphore. A message is usually received by a command’s communications department, reproduced, then distributed to staff members of departments concerned. It is tersely written, contains many abbreviations and is printed in capital letters.

However, when operations and time permit, timely news releases are transmitted in news style and contain all the information necessary for a good news story. Sentences are grammatically complete, including the necessary articles, adjectives and adverbs. A good message news release is very similar to newswire copy as it arrives in a radio, television or newspaper newsroom. It requires only copy editing and duplicating to get it ready for release to the news media.

A message news release is designated by the acronym PRESREL, which is a standard Navy communications abbreviation for press release. In the same line as PRESREL are the date and time (date-time group) the release was transmitted. For example: PRESREL 211802Z JUL 93. In this case, the story was sent on the 21st day of July, 1993, at 1802. The “Z” represents Greenwich Mean Time. The use of a different letter here would indicate local time in the area where the story originated.

All message releases are for immediate release unless otherwise designated. Occasionally, circumstances may dictate the use of such releasing instructions as: HOLD FOR RELEASE UNTIL (date and time), FOR SECURITY REVIEW AND RELEASE or FOR SIMULTANEOUS RELEASE. (Fill in the appropriate data.)

Because message news releases arrive printed in capital letters, you will use a different system for copy

editing. You must assume that all of the capital letters are lowercase and begin your copy editing from there. In other words, any time you want to capitalize a letter

you must underscore it three times. An example of a copy-edited message news release appears in figure 6-3.

CHAPTER 7

GATHERING AND DISSEMINATING NAVY NEWS

To gather and disseminate news, you must first know what news is and how and where to find it.

News is new information about anything. It is material previously unknown (or at least unpublished) that the public, in whole or in part, needs or wants to know. News also can be thought of as information that someone or some group, such as the Navy, wants the public to know.

A fundamental definition of news—a key part of newswriting—is basic to a journalist's understanding of the craft. Some think of news as a combination of the compass points: north, east, west and south. Although this is not strictly the meaning of the term, the idea does emphasize the broad dimension the field covers. News is everywhere.

The primary commodity of the mass media is news. This commodity is mass-produced by world events and is retailed in printed, pictured and spoken form to millions of customers. As a Navy Journalist you are a middleman for this commodity. However, you handle only the portion known as **Navy news**.

In chapter 2, you learned what news is and the ways in which it is presented to the public. In this chapter, you will learn the types of news sources and the methods used to obtain and distribute news (see fig. 7-1).

TYPES OF NEWS SOURCES

LEARNING OBJECTIVE: *Identify the types of news sources used in producing and disseminating Navy news.*

For an energetic and resourceful journalist, the avenues for finding news stories are limitless. In reality, however, you will find that your job in the Navy does not give you the luxury of spending days, or even hours, tracking down elusive leads that may eventually result in one story.

As stated in chapter 1, the Navy Journalist is a public information specialist, and not a free press journalist. Your job is to tell the Navy story. That means you must write positive copy about your command and its people (save adverse news

Figure 7-1.—Military news conference photo.

(Photo by: Chief Photographer's Mate Dolores L Anglin)

situations). You are employed by the Navy. Therefore, you are expected to **work for** the Navy.

This is especially true regarding a ship or station newspaper to which you may be assigned. Such publications may be compared with the house organs of civilian businesses covered in chapter 4. Their purpose is to inform, educate and entertain their readers and to provide a means of recognizing the achievements of the personnel in the organizations they represent. They are not intended as forums for expose'.

WRITTEN COMMUNICATIONS

When performing your job as a Navy Journalist, you will find that there are three primary sources of Navy news. They are as follows:

- Messages, directives, electronic mail and official correspondence
- Special contacts (both official and unofficial) maintained by the public affairs officer and his or her staff
- The future file

Information about practically every significant event that occurs in the Navy is passed on to those concerned via messages, directives, electronic mail or official correspondence. This includes news of coming

events; current fleet exercises and operations; collisions at sea; search, rescue and salvage operations; plane crashes; acts of heroism; weather warnings and unusual weather conditions; changes of command; personnel promotions; new performance records; participation of Navy teams in athletics; upcoming charity drives and countless other occurrences.

Messages

Messages are transmitted between commands by rapid means, such as radio, teletype and flashing light. When a message arrives aboard ship or at a shore activity, a number of copies are made and distributed to various departments. The PAO normally gets copies of all message traffic that might be of interest in carrying out PAO duties.

Information contained in a message is usually brief and tersely written. The information is seldom detailed enough to be used for writing a comprehensive story. However, the basic facts are included and they provide a good starting point for you to develop a story.

Directives

Directives provide another source of Navy news for release to the civilian news media. You will find that much of the information they contain is intended for use by Navy personnel. Information about pay and allowances, uniform changes, advancements and promotions, service members' and dependents' benefits, training and educational programs, new regulations, morale, leadership, charity drives and similar subjects are put out in directive form. When analyzed and written in news story form to play up local interest or some other news peg, information of this type makes good copy for command newspapers and other publications written primarily for a Navy-oriented audience.

Official Correspondence

Official correspondence between commands often provides tips for worthwhile stories. An Aviation Machinist's Mate first class, for example, submits an idea to the Naval Air Systems Command via the chain of command about an improved method for servicing aircraft. The idea is tested and adopted, and the individual is commended for the initiative and ingenuity shown. The entire transaction takes place on paper in the form of official correspondence. If copies of the letters are routed to the PAO for information, you

will have an opportunity to develop a good story for internal and external release if the facts are unclassified.

Security is an important factor for you to consider before using any information available in naval messages, directives and official correspondence for a news release. If the material is classified, you must not use it.

SPECIAL CONTACTS

Every public affairs office depends on tips from outside sources to develop stories. Regardless of the size of a command, it is impossible for you to know everything that is going on. By creating a list of special contacts, both officials and personal friends, and acquainting them with your job, you will assure yourself of having a steady flow of news items. Although a stranger may be reluctant to telephone your office and suggest a story, a friend or an acquaintance will feel free to call.

Officially, you should at least know the name, rank and title of every senior officer in your command. You should also have a good idea of the type of work they do and where they can be reached when you need information. If you remain in your job long enough, you will probably have personal contact with them. If you show them you are an efficient and capable person and establish credibility, they will be good sources of news as well.

You will find that your job is easier when Cmdr. Tilde, the medical officer, calls to tell **you** about a new medical device being tested at the clinic; or when PNC Umlaut informs **you** that the Navy's oldest enlisted man has reported aboard; or when Mr. Caret at MWR lets **you** know that a base civilian signed a minor league contract to play in the New York Mets organization; or when Lt. Breve announces to **you** that he is engaged to marry a former Miss America.

Eventually, all of these stories might have filtered down to the PAO, but the fact that you were informed firsthand gives you a head start on getting the story out while it is still news.

FUTURE FILE

Most public affairs offices should maintain a current listing of all events that have been scheduled or planned for the future. Material collected in the **future file** usually falls under the heading of **created news**. The public affairs office develops the ideas, plans and

writes the stories, and releases them to achieve maximum dissemination.

The public visitation of your command, for example, is scheduled months in advance. To make sure the visitation is a success, the PAO embarks on a planned publicity program. Prominent public figures are invited as guest speakers. Displays and exhibits are set up. Parades, reviews and drill team demonstrations are planned. An air show, ranging from a simple, low-level flyover to unique maneuvers of the famed Blue Angels, may be scheduled. A steady flow of releases about the program plans is sent to news media to attract attention and visitors. Another event similar to public visitation is a planned, detailed program about the construction of a new ship, especially a new type of ship. A public affairs program is generated for the keel laying, building, christening, launching, fitting out, commissioning, sea trials, assignment to fleet and force commanders and finally, the shakedown cruise.

However, not all material developed by the PAO takes place on such a large scale. A visit by an important dignitary, a CO's speech, the return of a ship from extended operations, special anniversaries, observances of national holidays in conjunction with the civilian community and athletic and entertainment events that will benefit charities are all created news items included in the future file. The PAO gives these events advance buildups, spot news coverage and occasionally, follow-up coverage.

The future file is usually a collection of file folders, each one containing advance information about a particular upcoming event. It can also be as simple as a calendar pad with enough space in its blocks to write key words that serve as reminders. A wall-sized grid under plexiglass works well too.

Another variation of the future file is the date-box. This consists of 31 file folders containing advance material for each day of the month.

Whatever arrangement is used, all public affairs offices should maintain a good tickler system of upcoming events to assure complete coverage of all news events.

METHODS OF GATHERING NEWS

LEARNING OBJECTIVE: *Recognize the most commonly used methods of gathering Navy news.*

The four most commonly used methods in news gathering used by Navy Journalists are observation, telephone conversations, research and interviews.

OBSERVATION

Observation consists of your actually seeing an event take place and then reporting what you have seen in the form of a news story. The difference between a good story and a poor one is often in the skill of the observer. Skilled observers use their eyes, ears, mind, notebooks, and tape recorders. They make sure they get the concrete facts, specific figures and accurate information. They look for the colorful, the dramatic or the unusual in any situation.

Skilled observers always try to get more information than they actually need. They know it is easier to discard excess material than to retrace their steps after the story is cold. Developing your powers of observation can come only through experience. You cannot become a skilled observer by simply reading a book. The key to becoming a good observer is to look for more than you see on the surface.

THE INTERNET

One of the most common sources of information today is the Internet. Nearly every Navy command has its own official command World Wide Web Site. These sites provide valuable information on the makeup of the command, command history and special events. An advantage to using the Internet is that the information is regularly updated and remains more current than other sources.

Information taken off the Internet must be downloaded to your work center computer, stored on a diskette and then compiled. Be careful to check everything you download for viruses before opening them on your work center computer station. A computer virus can wreak havoc with your PC and any computers you transfer or share information with. Contact your command Information Systems Security Office to ensure your work center PC has the latest computer virus protection software.

Once you have downloaded, checked for virus, and compiled the information, electronic transfer is swift and easy.

TELEPHONE CONVERSATIONS

The telephone plays an important role in your daily work as a journalist. It saves you time, legwork and

often allows you to reach people who are ordinarily too busy to see you in person.

Telephone conversations may range from full-scale interviews to brief queries to verify or amplify information. But regardless of how often you use this method of newsgathering, you should keep the following points in mind:

- Know what information you want before you dial. Keep your pencil and paper handy. Do not call someone and then ask that person to wait while you look for writing materials.
- Speak politely in distinct, well-modulated tones.
- Be cheerful and businesslike.
- Make sure you get your facts straight. Ask the other person to repeat figures or spell out names.
- Avoid three-way conversations among yourself, the person on the telephone, and somebody else in your office.
- Recheck your information by reading it back to the person who has given it to you.
- Record the conversation using a “telephone pick-up” (device that attaches to the telephone receiver and plugs into the microphone jack of the cassette tape recorder). To avoid “privacy” problems, inform the person on the other end that you are recording the conversation for note-taking purposes only.
- Do not discuss classified information.

Although a telephone is a very useful instrument, remember it is not the only, and not necessarily the best, method of gathering news. It should supplement, but not replace, all other methods. Whenever it is proper and convenient, use the telephone, but do not be afraid to engage in a little legwork.

RESEARCH

Research is nothing more than digging out information from files and reference works. Research is used to verify or amplify facts in news stories and to give depth to feature stories and magazine articles. Very few Navy public affairs offices have adequate reference libraries. To do any extensive research, learn to use the facilities of the nearest Navy, public or college library. Here you can find the necessary books, encyclopedias, almanacs, magazines, atlases, directories, indexes and similar references. The Naval Historical Center (OP-09BH), Washington, D.C., is a

good source of additional information about the Navy (www.history.navy.mil/index.htm).

INTERVIEWS

About 90 percent of everything in a news story is based on some form of interviewing—either in person, by telephone or occasionally, by correspondence.

As a Navy Journalist in search of information, you must learn who to get information from and how to record facts. You must learn techniques for handling different kinds of people—how to draw some out, how to keep others on the topic, and how to evaluate the motives or honesty of others. In short, you must learn how to get along with people and how to treat them with tact and understanding while still accomplishing your purpose (see fig 7-2).

INTERNET WEB SITES

Some of the official Navy world wide web sites that could be accessed for information include:

U.S. Navy Homepage:	www.navy.mil
CHINFO:	www.navy.mil/chinfo
Navy Historical Society:	www.history.navy.mil
BUPERS:	www.bupers.navy.mil
CNET:	www.cnet.navy.mil
Navy Exam Center:	www.cnet.navy.mil/advancement
Naval Media center:	www.mediacen.navy.mil

For a list of all official Navy web sites, visit the official U.S. Navy homepage.

Figure 7-2.—Media interviews require careful planning.

(Photo by PH1 Michael Wormer)

Types of Interviews

A distinction must be made between news stories that are merely based on interviews and actual interview stories. Very seldom is a journalist present at the scene of an accident as it takes place—for example, at a collision between two automobiles. A story of this type must be based entirely on interviews—either in person or by telephone—with the police, with eyewitnesses, with the victims themselves, and depending upon the gravity of the accident, with the garage mechanics, hospital attendants, relatives of the victims and others.

In news stories of this kind, the journalist is concerned with a news event that requires interviewing people to learn the facts. The **interview story**, on the other hand, is essentially a feature built around the views, personality or exploits of an individual or group of individuals. The difference, in most cases, is largely in the emphasis. In writing the **interview-based news story**, you stress the news, whereas in the **interview story**, you place the stress on the person being interviewed.

Interviews are as varied as the people who grant them, the journalists who conduct them and the news that suggests them. Rarely are interviews so mechanical that they can be reduced to standard formulas or categories. Several types, however, deserve special attention because they are the ones that occur most frequently. They are as follows:

- News interview
- Telephone interview
- Casual interview
- Personality interview
- Symposium interview
- News conference
- Prepared question interview

NEWS INTERVIEW.—The news interview is based on “hard news,” some event or development of current and immediate interest. Suppose you are a journalist assigned to the staff of Commander, Naval Air Force, U.S. Atlantic Fleet (COMNAVAIRLANT), and a new supercarrier has been launched for the Navy. Later, you learn the carrier will be assigned to the Atlantic Fleet, and you are assigned to write the story. The original news announcement released by the shipyard or naval authorities would most likely contain

only the broad, straight facts—cost, size and construction details.

A story of this scope is of major interest to the local community of the supercarrier’s homeport. Media want more information than is offered in the initial report. By interviewing competent news sources, such as key officers on COMNAVAIRLANT’s staff, and asking well-defined, carefully considered questions, you can localize, illuminate, expand and add depth to the original story. When will the ship be commissioned? How will the ship’s presence affect the local economy? What will its mission be? When is it expected to join the fleet? To which carrier division will it be assigned? Will there be a flag officer embarked? Has a prospective CO been selected? How will this new carrier strengthen our national defense effort?

In any interview, try to speak to the best authority available. Do not settle for the supply clerk, if the information you need should come from the CO.

TELEPHONE INTERVIEW.—The telephone interview, a modified version of the news interview, has a number of obvious advantages, and at the same time, it has several limitations that challenge a resourceful journalist. Ingenuity and clear thinking are sometimes needed to locate a news source when a big story breaks; the power of persuasion is often necessary to elicit information from a reluctant person who can easily hang up the receiver, and a sympathetic telephone voice is important when you are talking to a family where tragedy has struck.

CASUAL INTERVIEW.—An accidental encounter between a journalist and a news source on the street or at a social gathering can often result in a tip that arouses the curiosity of a writer. A major news story may be the result after you do some digging.

PERSONALITY INTERVIEW.—In the personality interview an effort is made to let the reader see the appearance, mannerisms, background and even the character of the subject. Magazines like the *New Yorker* have developed this type of interview, called “a profile,” into a high art not easily attained by daily newspapers under the pressure of deadlines. However, with preliminary research on an interviewee’s background, intelligent planning of questions and skillful interviewing, a good journalist can let a person’s words and mannerisms bring that individual vividly to life in an interesting newspaper feature story.

SYMPOSIUM INTERVIEW.—From time to time, news developments of current interest require a journalist or a team of journalists to seek information not from one or two sources but from a dozen, or perhaps a hundred or more. For example, which of the two presidential candidates in the television debate made the best impression on the public? How do the residents of a city feel about their football team winning the Super Bowl? For some stories—as in a pre-election poll—all of the techniques of a scientific opinion sampling may be required. In other instances, reactions and comments may result in a lively feature story. Depending on the subject, the symposium (or group) interview may bring out opinions of importance, entertainment or merely the views of the “man on the street” on some subject of general interest.

NEWS CONFERENCE.—Since the 1960s, one of the most popular methods of getting news is the news conference. By presenting news conferences “live” on television, President Kennedy raised them to one of the most potent forces in the public exchange of opinion between the people and their government. Today, every level of the government uses the news conference to release sensitive information in a timely manner. For close to 70 years, in a different format, the news conference has been an important source of news. The person interviewed at a news conference may be the President of the United States, the Chief of Naval Operations, a senior government official, the manager of a big league team, a movie star plugging a new motion picture or any other person promoting what is believed to be a news story of interest to the public. As in every interview story, preliminary groundwork pays off; a knowledge of the interviewee’s background is indispensable. During the interview, an alertness to story possibilities often leads to unexpected results. Additional details on news conferences are covered later in this chapter.

PREPARED QUESTION INTERVIEW.—When direct person-to-person questioning cannot be arranged with an important news source, journalists occasionally resort to giving that source a set of prepared questions to which a reply is requested. More often than not, however, the questions go unheeded. When the journalist does get a reply, a major news story generally results.

In every interview assignment, the journalist’s objective is always the same—to ferret out as much news, details, significance and color about a personality or event as possible. The success of the story depends on the quantity and quality of the

information gleaned from the interview and the journalist’s sense of news values and writing ability.

Interview Tips

The manner in which you prepare for conducting interviews can often determine the success or failure of those projects. What follows are 10 tips on handling interview assignments that should prove useful to you.

1. **Know what you want.** Whether you are interviewing someone for a hard news story or you are on an assignment for a feature, remember you are the one who will have to write the story. This means that you must bear in mind the essence of the story you are after or the angle you want to develop. If you are covering a fire, what are the things you should find out? They will include whether anyone was hurt, the extent of the damage, the cause of the fire, how it was discovered, which fire stations responded, how long it took to put out the blaze and many other facts.

The same kind of analysis must be applied to all stories. This will guide you in your questioning, and most important, in your search for details. Learn how to dig for facts. Be alert, interested and curious. Details are more vivid than generalities. For example, if your subject casually mentions he was the editor of a college newspaper, find out the name of the college, and when the position was held. These are simple, natural questions that will come to the minds of some of your readers; do not leave them unsatisfied. Every story is unique. It will differ from others in many details. Unless you know what to look for and how to get it through proper questioning, your story will be incomplete.

2. **Prepare for the interview.** Whenever possible, particularly on a feature assignment, look up your subject’s background. From news clippings or from reference works like *Who’s Who*, try to determine beforehand any views the individual may have on the topic of your interview. Ignorance of an important person’s biography and work may seem insulting to the individual concerned, and you may lose the person’s cooperation. However, you should never try to impress the interviewee with your knowledge of the individual’s own subject.

3. **Plan your questions.** This does not mean you should read them formally or present them in an artificial manner. Conduct your conversation in a natural, informal fashion. Always keep your questions in mind and try to guide the conversation along lines that will give you a story with substance. Planned questions,

jotted down on a pad in front of you, are particularly valuable when you interview someone by using the telephone. At the same time, be receptive to a new angle that may arise and may be better than the one you had originally planned.

4. **Be careful about taking notes.** Some interviewers write everything; others write hardly a word. Some subjects become uncomfortable in the presence of a reporter transcribing every word they say and at the prospect of having their names appear in the paper. Other interviewees prefer to have their words written down to avoid being misquoted. In general, you will probably remember most of the conversation if you write the story while it is still fresh in your mind. Details, such as names, dates, statistics, key words and distinctive phrases, should, of course, be jotted down on the spot.

If you have access to a small, portable tape recorder, by all means use it. Some subjects may be uncomfortable in the presence of a tape recorder, but most will not. Try to use a tape recorder with a built-in microphone. This will avoid the sometimes-awkward practice of holding a hand microphone to the interviewee's face.

5. **Know your subject.** Some people need to be flattered; others cajoled. Some are naturally shy; others will talk a blue streak. Evaluate your interviewee and guide yourself accordingly. The majority of people will react favorably to a straightforward, factual approach and will not be impressed by arrogance or excessive humility. Only courtesy, intelligent curiosity, a sincere desire to be natural and knowledge of what you are after will help you come away from an interview with a newsworthy story.

These are major principles that can be applied in nearly all interviews. However, as previously mentioned, alert and resourceful journalists must be ready to vary their techniques depending on the temperament and views of the interviewee, the nature of the story and the dictates of circumstances.

6. **Be specific.** A question like "Anything new?" will, in most cases, bring forth very little information because the average layman knows little about what is of news value. Ask direct and leading questions.

7. **Be accurate.** The smallest error can cause embarrassment and even a libel suit. Do not be afraid to ask questions and to check facts. When you interview someone by using the telephone, one letter can easily be mistaken for another. Therefore, spell out names by using phonetic aids. Spell it: "S-M-I-T-H. S as in

SIERRA, M as in MIKE. ..." (Of course, make sure it is "Smith" and not "Smythe.") People dislike having their names misspelled. Also, obtain the complete and correct addresses of people in a story.

8. **Look for color.** In personality features, particularly, an apt word or phrase describing your subject's appearance or mannerisms will help your readers "see" the person. Here is a helpful suggestion: As you conduct the interview, try to think of words that would best describe your subject in a nutshell. In some stories, a reference to a person's movements, gestures, way of talking, and his or her surroundings may give a better picture of that individual. Often, you will be able to make some comparison in terms of a figure or object familiar to your readers, but be careful not to offend the interviewee.

9. **Do not talk too much.** You are interviewing someone to **get** information, not to demonstrate how smart you are. At the start, you may need to lead the conversation along general lines to put the interviewee at ease and to get around to your subject. But after that, be self-effacing. On occasion, you may have to play dumb; then assume nothing and ask everything. Be conscious of time; do not waste yours or the interviewees. Occasionally, a time limit is imposed on an interview. When time is limited, you will have to arrange your questions in order of importance. Although the relationship between you and your subject should be informal, remember that the nature of your call is business, not social.

10. **Remember your sense of humor.** This may break the initial ice or even save your interview if the interviewee has a negative attitude.

One final thought —the best kind of interview is one that proceeds in a friendly, natural, informal way. There was a time when some news people thought little of using deception or impersonation to get the information they wanted. Respectable newspapers and other media frown on these practices today.

Additional information on interviews may be found in chapter 15 ("Radio and Television Interviewing").

AUTHORITY FOR RELEASING NAVY NEWS

LEARNING OBJECTIVE: *Identify the proper authority for the release of Navy news.*

When information previously limited to a controlled number of persons is made available to the general public, it is said to be “released.” If this is done in formal written form, the document itself is termed a **release**, or a **news release**. Officers in command of all ships and stations, as well as senior commands, are authorized to release certain types of news without requesting advance approval from higher authority.

News of purely local interest is the first of this type. However, there are certain cautions. All officers in command are responsible for keeping CHINFO and other concerned seniors informed of all events and actions when any possibility exists that the national news media may become interested. There are also special procedures for handling news releases relating to members of Congress and civic officials.

Spot news, including announcements or answers to queries of an emergency nature, where delay in issuing information would be harmful to the best interests of the Navy, is releasable without advanced approval of higher authority.

Categories of news releases for which local release is not authorized, without prior approval of higher authority, are covered in detail in *PA Regs*. A partial list of these categories is included in table 7-1.

In some cases the PAO is authorized by the officer in command to release certain news items, such as “hometowners” and news of a purely routine nature.

Release of information by any command is carried out by, or with, the assistance of the command PAO. Offices or divisions within a command cannot release information to the public without consulting the PAO.

For a complete study on the proper release of information through channels from the heads of government down to individual units, refer to the most current version of *PA Regs*. It describes the procedures for releasing news at all levels of interest —local, regional, national and international.

METHODS OF DISSEMINATING NAVY NEWS

LEARNING OBJECTIVE: *Determine the methods of disseminating Navy news.*

Navy news material, properly authorized for release, can be channeled to the media in several ways. The nine commonly used methods are as follows:

- Standard Navy news release

Table 7-1.—Subjects Not Releasable Locally (Unless Approved by Higher Authority)

A. Accidents and Casualties

1. Civilians on board Navy ships, etc.
2. Foreign nationals in training with the Navy
3. Involving more than one service
4. Nuclear
5. Names and photographs of casualties

B. Biological Research, Chemical Warfare and Psychological Warfare Programs

C. Classified Information and Intelligence Activities

D. Foreign National and Foreign Countries

1. Policy
2. U.S. foreign defense plans
3. Operations and training exercises

E. Movements of Units

1. Between ports in the U.S.
2. Overseas areas

F. New Weapons and Equipment

1. Performance or capabilities
2. Modifications resulting in improvement

G. Nuclear

1. Nuclear propulsion
2. Nuclear weapons capability of U.S. forces
3. Port visits of nuclear-powered ships
4. SSB(N) operations

H. Personnel

1. Movements of
2. Name and address lists (example: “FOUO” directories)
3. Reduction in personnel
4. Statistics

I. Scientific Results (unclassified)

J. Submarine Sightings

K. Supply

1. Sources/quantities of strategic or critical supplies.
2. Movements, assembly and storage of supplies/ materials

M. Training of Specialized Units

- News advisory
- Spot news announcements
- News conferences

- Interviews
- Background briefings
- Feature releases
- Advance releases
- Personal appearances

STANDARD NAVY NEWS RELEASE

A Navy news release is an official Navy statement prepared in news story form. The enlisted journalist normally prepares and edits it, then the PAO, through the authority of the officer-in-command, approves the release. As a Navy Journalist, you will work with the Navy news release more than with any other method of news dissemination. A well-prepared and edited standard Navy news release—placed in the hands of all interested media at the same time, supplying all with identical information—remains the most satisfactory method of releasing news.

Most public affairs offices, particularly at larger commands, use a printed heading for their news releases. These are attractive and help members of the media identify the source of the release more quickly. However, they are by no means necessary. If a printed heading is used, keep it simple, informal, suitable and in good taste to cover all types of releases. The news value of the material, and not the packaging, is the most important consideration. A sample release format is shown in tables 7-2 and 7-3.

Certain information, however, should always be included in the heading of a release. Make sure your release format includes the following items:

- Name, address, ZIP code and electronic mail address of the originating command
- Office telephone numbers (including facsimile number)
- Point(s) of contact for further information
- Type of release
- Release number
- Short headline to identify the content of the release
- Date of release

News releases should be double-spaced, typed on only one side of a sheet of paper and legibly reproduced. Official directives regarding economy in duplication on both sides of the paper do not apply to news releases.

Timing of Navy News Releases

The timing of news releases is almost as important as their content. An improperly timed handout may be lost in the media editor's in-box simply because it is poorly timed.

Most Navy stories are distributed **For Immediate Release**. This authorizes the media to use the story as soon as it is received.

Occasionally, however, it is necessary to distribute a story on a **Hold For Release** basis. This tag, along with the authorized date of release, is attached to important feature stories. It is usually typed in the spot where **For Immediate Release** appears in table 7-2.

Assume that the CNO accepts a speaking engagement in your city. If an advance copy of the speech is available, it may be released to news media on a **Hold For Release** basis. This would give news media several advantages. First, reporters covering the event would not have to take notes of the speech. They would merely check their future release to make sure the CNO followed the text. Second, television or radio people may not want to record the entire speech. With an advance copy of it in their possession, they could tape only key portions. Third, if the speech is important enough, newspaper editors may decide to publish it verbatim. The advance copy would permit them to set the speech in type beforehand so the speech could be printed immediately after it was delivered.

In general, however, news media prefer to use news as soon as it is received. Reporters take pride in bringing facts to light, not in withholding them. Never give them a story marked **Hold For Release** unless you have a good reason.

News Release Numbering System

For quick reference and orderly filing, a release number is assigned to all outgoing stories. There are various systems of assigning release numbers. Most commands follow the practice of beginning a new series at the beginning of each year. The first release sent out in 2001, for example, would have a release number of 1-01. The second release would be 2-01, and so forth. All releases are numbered consecutively in this manner until the end of the year. Remember that release numbers are assigned to each story, not to each copy of a story. If one release is sent to 17 different media, all 17 copies should bear the same release number.

OFFICIAL NEWS RELEASE

FOR IMMEDIATE RELEASE

**RELEASE #12-94
FEBRUARY 2, 1994**

SHORT HEADLINE HELPS EDITORS IDENTIFY STORY'S NEWS PEG

WITH THE FIRST FLEET, February 2 — This is the recommended first-page format for Navy news releases. It is for immediate release under a dateline. The "heading" contains the office of origin and its mailing address, telephone numbers, fax number, point(s) of contact for further information, type of release, release number, headline and date.

Other recommended styles of datelines are as follows:

1. For releases originating ashore:

SAN DIEGO, Calif., Feb. 2

2. For releases originating at sea:

ABOARD THE USS CONTOUR INTEGRAL AT SEA, Feb. 2

If there is more than one page of copy in a Navy news release, end each page, except the last, with the word "more."

-more-

Table 7-3.—Sample Navy News Release Format (page 2 of 2)

**NS WEIERSTRASS PAO
NAVY NEWS RELEASE FORMAT
2-2-2-2-2**

Second and subsequent pages of the release should be "slugged" for identity and numbered as shown above.

Do not hyphenate words between lines, and do not break sentences or paragraphs between pages. Paragraphs are indented five spaces. Begin your first paragraph about one-third to one-half of the way down the first page.

The copy itself should be neatly typewritten, double-spaced in lines 60-75 characters in length with one-inch or better margins all around. This allows the editor to edit or make notes on the release.

Use a high-speed copier when several copies of a release are necessary. Make sure each copy is legible. When a number of pages are involved, check to see that the pages are in order and that there are no blanks.

Remember, do not clutter an editor's desk with a news release unless you are telling him something newsworthy.

Finish your story on the last page with either "-30-", "-end-" or "-USN-" to indicate the end.

-USN-

NEWS ADVISORY

A news advisory is an abbreviated form of a news release intended to get the news media to cover an event themselves. The news advisory is normally no more than a page in length and includes a compact description of the event. Pertinent information, such as the date, time, location, specific details, and the significance of the event, also should be included. You may disseminate the news advisory in the same manner as a news release, using the format in table 7-2.

SPOT NEWS ANNOUNCEMENTS

When an event of immediate and urgent news interest occurs within the command, such as an unscheduled VIP visit or an accident involving casualties, all available and properly releasable facts are issued promptly and without waiting until a complete account is compiled. Spot news of this type is usually released by bulletin or in memorandum form. However, if circumstances require, it may be read over the telephone. Spot news is always issued **For Immediate Release**.

NEWS CONFERENCES

Whenever a news event is of great importance to the local public or when there is a visit by a prominent official who wishes to address the media, a command calls a news conference and sends invitations to all interested media. Information is released at a news conference through a senior naval officer or other Navy spokesperson, an individual involved in unclassified activity of public interest, an expert in some newsworthy project, survivors of an accident, or perhaps someone directly involved in some activity or event.

Often, after an advance release goes out announcing the intended visit of a VIP or some other event of significance, the media requests a news conference.

When time permits, prepare media information kits (covered in chapter 16) to supplement information made public at news conferences.

Avoid, if possible, requesting media to submit questions in advance. When advance questions are desirable, as in cases where highly technical answers would be required for some questions, correspondents should be advised of this. When written questions are volunteered, detailed answers are normally prepared

and distributed to all attending media representatives immediately preceding the conference.

A news conference can be abused. The only reason to call a news conference is to release information that cannot be covered adequately by a news release. A news conference should not be used solely as a prestige vehicle. It should be called only when there is something to say. Most media cannot spare the time and personnel for this type of coverage. The quickest way to alienate reporters is to make them cover an event in person when they could have covered it over the telephone.

A news conference can do a lot for the Navy when it is used properly. News conferences establish public esteem, erase controversy, and show that the Navy has nothing to hide. Reporters are given the opportunity to ask questions and get all the information they want. This often results in clearing up misunderstandings. Finally, it enables all media to get the same information at the same time.

INTERVIEW

An interview differs from a news conference in that it is usually initiated by a media representative and involves communication of information from a responsible spokesperson to only one reporter.

BACKGROUND BRIEFINGS

Background briefings differ from a routine news conference or interview only in their usual provisions that a precise source is not identified in the reporters' stories. The content or source of a story written from a briefing is usually attributed to a "Navy spokesperson," "informed military sources" or some other truthful, but not specifically identified, individual imparting the information. In such cases, the ground rules are clearly understood and agreed to by all participants. In most cases, especially when the subject is not of a technical nature, these briefings are conducted by the command PAO.

FEATURE RELEASES

Features, or "time releases," differ from spot news mainly in the degree of immediacy. That is, it makes little difference whether particular news accounts are passed along to the general public today, tomorrow or next week.

A feature may concern previously undisclosed developments dating well into the past or some

upcoming event or anniversary. Either way, it must contain a high degree of general human interest. This type of release is usually made in writing, but it may be given out through an interview or news conference. Often a feature release lends itself to pictorial treatment by the use of still photographs or videotape. Feature releases are issued for both immediate and future use.

ADVANCE RELEASES

You read about advance releases (stories) in chapter 5. Advance releases are issued concerning events scheduled or anticipated for the future. They are generally on a **Hold For Release** basis, specifying exact times, to make sure of simultaneous use by all interested media, and to prevent premature disclosure. An advance release often is accompanied by an invitation to media representatives to attend an event

and is usually supplemented by follow-up releases. Official photographs, printed programs or other material providing in-depth background on a forthcoming event are often enclosed with an advance release.

PERSONAL APPEARANCES

Personal appearances include formal speeches and informal remarks by Navy officials and authorized spokespersons in which information is released to appear as an official news announcement. The information could be given at public or semipublic meetings, in public forums, on radio and television programs or during any other contact with the public. The size of the group being addressed is irrelevant, and it does not matter whether the remarks are or are not reported by the news media.

CHAPTER 8

PUBLICATIONS

Despite the popularity of radio and television, the Navy and the public-at-large are very much print-oriented. All large ships and stations and many of the smaller Navy commands publish newspapers, magazines and brochures regularly. Consequently, as a Navy Journalist, you can expect to be tasked with editing or assisting in the production of such a publication.

Should you somehow miss out on this challenging opportunity, a number of other items requiring an editor's skills and knowledge will likely surface on your desk some morning. Among these highly probable assignments are family grams, change of command programs, public visitation brochures and cruise books.

Therefore, the information in this chapter, while directed primarily to potential newspaper editors, also is intended to acquaint you with the fundamentals and terminology of laying out and making up copy for the publisher. Tips on designing Navy newspapers for a contemporary audience are included in this section as well.

DESKTOP PUBLISHING

LEARNING OBJECTIVE: *Define desktop publishing and explain its limitations and capabilities.*

In less than 10 years, desktop publishing has surfaced as one of the predominant personal computing applications. It has changed the way you, as a Navy Journalist, produce a wide array of publications, from ship and station newspapers and family grams, to welcome aboard pamphlets and commissioning/decommissioning brochures (see figure 8-1).

DEFINITION

Simply stated, desktop publishing is an application that combines an economical personal computer system with page layout software and a laser publisher to produce typeset-quality-printed products. This eliminates the need to work with dummy layouts and galley proofs because the entire product is composed on a computer screen.

Figure 8-1.—The components of a typical desktop publishing system: personal computer, laser printer, scanner, mouse and software.

Using computers to compose pages is now commonplace throughout the country. For many years, newspaper and magazine publishers have used computers for all facets of page layout and editing. However, the cost of their computer systems and accompanying software was prohibitive, and therefore, limited to national publications or those in relatively large markets. Accordingly, the manufacturers of customized computer publishing systems were hesitant to produce cheaper versions of their products. This changed in 1985 when desktop publishing went mainstream.

TRADITIONAL VS. DESKTOP PUBLISHING

Desktop publishing allows you to throw away your drafting board, paste-up sheet, “T” square, rubber cement and the rest of the printing and layout “tools of the trade” that were formally used to lay out pages.

Consider, for example, you are a JO3 tasked with laying out and designing page 5 of your weekly funded newspaper. In the old days, you would work with the newspaper dummy where you indicate the arrangement of the copy, headlines, photographs and cutlines. Your main tools would be a pencil, printer's rule and eraser.

If you worked the same page on a typical desktop publishing system (fig. 8-1), you will notice a tremendous difference. You may layout and design the entire page on the computer screen using a publication software program, the computer keyboard and a mouse. You could indicate the size and kind of type and its page position with relative ease. Using a scanner, you could insert illustrations and photographs into the layout; then make modifications as necessary. All the while you are working on-screen with body copy that will result in typeset-quality text —without the involvement of a military or civilian publisher.

STRENGTHS

With the proper computer hardware and software in place, you will enjoy the following attributes of desktop publishing:

- A cut in printing costs by as much as 75 percent.
- Fast turnaround time.
- Making corrections to spelling errors, omission of words or entire lines of text and poor word division at your office.
- Making last-minute changes without a major reworking of the paste-up.
- Using less office space, a key consideration especially aboard ship.
- Eliminating the need to work with a publisher on the initial paste-up of a product, as discussed earlier.
- Eliminating the need to work with the subcontractors of the publisher, such as typesetters, proofreaders and so forth.

WEAKNESSES

Any computer-literate JO can operate a desktop publishing system with relative ease. However, there are two common hazards you should recognize and avoid.

The old saying, “Familiarity breeds contempt,” certainly applies to desktop publishing. Some novice desktop publishers, convinced that the computer hardware and software are suitable replacements for talent and skill, become complacent in the basic principles of layout and makeup. In turn, they produce page layouts you would only see in your worst nightmares. Make sure you follow the

long-established rules of layout and makeup covered later in this chapter.

In addition, you should apply some forethought when selecting your computer hardware and software. On occasion, some hardware components will not function properly with others, and there are some word processing programs that will not work well with certain desktop publishing programs. If you are purchasing a new system, make sure you get satisfactory answers to questions about compatibility.

DESKTOP PUBLISHING SOFTWARE

LEARNING OBJECTIVE: *Identify the most common desktop publishing software and determine their basic features.*

There are several desktop publishing software programs for both Macintosh and PC-based computer systems. You should be aware that although these programs are similar in terms of overall operation, they vary widely in their capabilities and functions.

For instance, less elaborate desktop publishing programs are mainly suited for simple pamphlets and brochures, while more complex versions include advanced features, such as indexing, style sheets, and typographic operations you can use to control the spacing of single characters.

Since new desktop publishing software programs (and newer versions of existing programs) are introduced to the marketplace frequently, you should research the features of as many programs as possible. As stated previously, make sure the program is compatible with your hardware. It should be able to convert files from your current word processing program, have a good graphics file and a large selection of type fonts from which to choose.

NEWSPAPER FORMATS

LEARNING OBJECTIVE: *Recognize the types of formats of ship or station newspapers.*

The three formats used in ship and station newspapers are full format, tabloid and magazine. These formats are shown in figure 8-2 and are described in the following text.

Figure 8-2.—Formats of ship and station newspapers.

FULL FORMAT

A full-format (also known as broadsheet) newspaper is one that measures 16 or 17 inches wide and 21 to 22 inches deep. A full-format newspaper can be made to have five columns, six columns, seven and one-half columns, eight columns or nine columns.

TABLOID

A tabloid newspaper is about half the size of a full-format newspaper. It measures 10 to 12 inches wide and 14 to 18 inches deep. A tabloid format newspaper can have two, three, four, five, five and one-half and six columns.

MAGAZINE

A magazine-format (also known as compact) newspaper is about half the size of a tabloid newspaper. It measures 7 to 8 inches wide and 10 to 11 inches deep. It can be made to have one column, two columns, and three columns.

NEWSPAPER DESIGN

LEARNING OBJECTIVE: *Recognize the techniques used in ship or station newspaper design and any specific considerations, respectively.*

Other important considerations (beyond the news gathering, news writing, and copy editing aspects covered in the preceding chapters) are the techniques

for putting the material together so that your paper emphasizes what is important. You will also need to know what makes an attractive appearance and draws and holds the reader's eye. All of this is done through good layout and makeup designed to achieve the best overall appearance and style of the publication and to allow the reader to obtain the maximum information in the shortest time.

Layout is the planning of the position and page that each piece of copy or art will occupy in your publication. This includes your choosing the styles and sizes of headlines desired, the kinds and sizes of type to be used and deciding how to use them, and indicating these plans on the layout sheets.

Makeup is normally the execution of that layout by the publisher (the compositor), although sometimes the terms *layout* and *makeup* are used interchangeably. For instance, the name "makeup editor" is used on some newspapers instead of "layout editor."

THE DUMMY

Indicating on the layout sheet where each element will be placed (sometimes called dummieing or roughing in) may be done as each segment of material is forwarded to the publisher. Some publishers will even give you rough proofs of galley type, headlines, and art and let you make a paste-up dummy on a layout sheet. Paste-up dummies ensure a high degree of accuracy in page makeup because they give the publisher a better overall picture of what you want. Do not confuse a paste-up dummy with a paste-up for photo-offset work. A paste-up dummy is merely a guide for the publisher; a paste-up for photo-offset is smooth copy to be photographed for printing.

THE BLUEPRINT

The blueprint for a newspaper is its layout sheets, or dummies, on which a detailed plan or sketch shows the arrangement of art, heads and copy to guide the compositor in making up the actual pages. Figure 8-3 is an example of such a dummy, and figure 8-4 shows the finished product that resulted from it.

The layout is an absolute necessity if you are to avoid the amateur editor's nightmare — finding out the day before publication that you have only eight pages of material for a 12-page publication. What is more, if you piece together a publication at the last minute without a layout—throwing in an article here and a

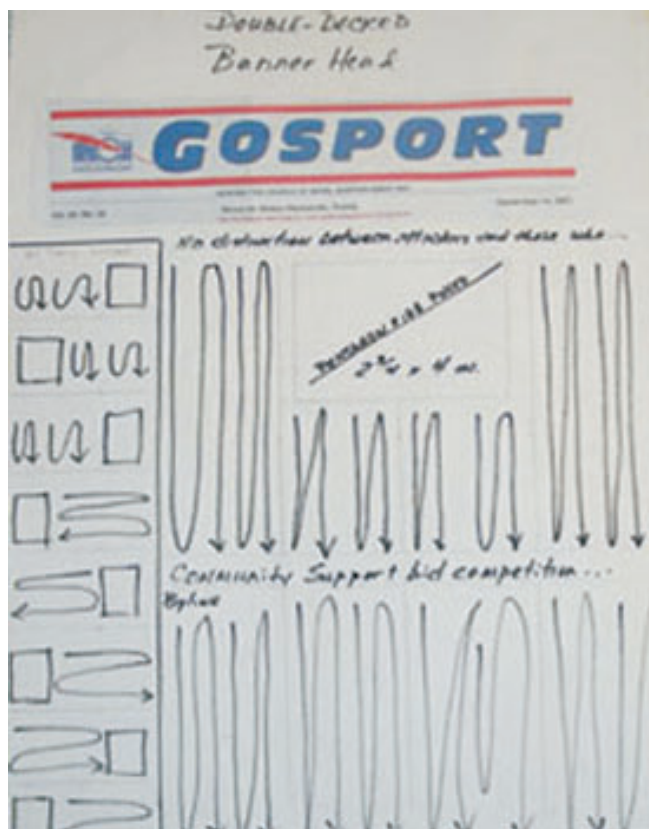

Figure 8-3.—Newspaper blueprint (dummy).

Figure 8-4.—The finished product based on the blueprint. layout in figure 8-3.

picture there—you will come up with a meaningless hodgepodge.

Whether you consider layout an art or simply a mechanical skill, it is clearly an involved, demanding function. You must acquire the following skills to become a good layout editor:

- A keen news sense to know which stories to emphasize and how strongly to emphasize them
- A good working knowledge of typography
- An understanding of graphic design principles and techniques
- A familiarity with modern newspaper design techniques

Layout duties on ship and station newspapers are usually handled by the editor, associate editor and subordinate editors (sports, leisure and so forth). On large commercial dailies, front-page layout is usually done by one of the executive editors—managing editor, news editor or copy editor—to ensure top-level emphasis of particular stories and ideas. Other pages are done by department editors (sport, feature, editorial) and by copy editors.

Remember: your layout is your blueprint, and blueprints are drawn to scale. So start by making up a standard layout sheet, showing the page with its columns drawn either to scale or to size. (A layout sheet of actual page size is the easiest to use.) The layout sheet should be marked for column widths. The top of each page should allow space for showing the issue, the page and the section of the paper. The best way to indicate where a story goes is to write in the story slug (the short identification line that goes right before the writer's name on a piece of copy), as shown in figure 8-5. You can use keys for art and your headlines can be written in.

COPY FITTING

As a layout editor, you must be able to determine an approximate length, in column inches, of a story from typed copy. (A column inch is one inch of copy, measured down the column, regardless of the column width being used.) By making a few simple calculations, you can determine beforehand how much space the typed copy will fill when it is set in type (on the basis of 2 3/8-inch or 14-pica-wide column—six picas equal one inch). For most 10-point type, three typewritten lines, 60 characters wide (on a regular 8 1/2- by 11-inch sheet of paper) equal one column inch

THE AMPHIBIAN
Amphibious Force Pacific Fleet

Record EM Advancements
Predicted for Test Takers *A - line, 2 cl.*

Exams 1/1/1
JOSN Jackson

10 pt, 2 cl. line

Navy Enlisted who have just completed taking the March advancement exams should be happy about a recently-completed planning report which forecasts a "projected" total of more than 122,000 vacancies in pay grades E-4 through E-7 during 6 months covered by the promotion cycle.

The figures indicate promotion spots will be available for more than 5,800 new chiefs, more than 15,000 new first class petty officers, nearly 42,000 second class POs and more than 58,000 third class petty officers.

14

Last August, 103,000 promotions were forecast, and more than 105,000 had earned their new stripes by December. The totals could go higher than the predicted 122,000 when the final returns are in, sometime this summer.

If qualified test-passers can be found to fit the predicted vacancies, the March tests seem likely to produce the largest crop of advancements since the Navy went to the bi-annual promotion cycle.

-more-

Figure 8-5.—Copy as marked for the publisher.

of copy. If other than 10-point body type is used, check with your publisher. Your publisher will provide for you a simple fitting formula for all sizes and styles of typefaces available, taking into consideration such things as variations in column widths, differences in fonts and so forth.

While it seems easier to simply take a story file from a disk, insert it into your software and then make the story fit your space, it is recommended that you plan your layout ahead of time using the layout steps mentioned previously so that you become familiar with the method.

Before forwarding your copy to the publisher, mark it clearly with all necessary instructions (guidelines) for the typesetter. If the publisher is going to make up the entire page from your layout plan, a piece of copy must contain the following notations:

- A key to its position in the layout (shown by the slug on the story and the slug on the dummy).
- The type and size of headline according to a headline chart (see chapter 9).

- The specifics on the size and style of typeface (if it varies from the standard body type previously agreed upon between you and the publisher).
- The column width (one column, two columns and so forth, should be designated by picas to avoid confusion with column inch measurements).

Once your layout is completed, you should be able to relax. A good publisher can make up your pages exactly as you want them from your blueprint, as long as you have provided the necessary information.

This section has covered layout techniques for offset printing, but most of the basic ideas covered here also can be applied to desktop publishing, including brochures, newsletters, Familygrams, newspapers and web sites.

GRAPHICS AND IMAGES

Desktop publishing software has made the insertion of photos and graphics into your publication, one of the most tedious and time-consuming tasks in the past, into one of the easiest.

Images can be stored on a computer's hard drive or on a disk, and easily inserted into the software program. In this computer-literate society, almost anyone can take and process digital images. But in newspaper and other publication processing, images almost always need some sort of editing to fit the space allotted in your publication. Whether it be enlarging, cropping or fixing the color (or black and white) resolution of your photos or graphics, you will rely heavily upon another computer software program to edit these images.

PRINCIPLES OF IMAGE EDITING

It is important to remember that even though you may be working with a digital image instead of a photograph taken with a 35mm Single Lens Reflex (SLR) camera, there are many rules you need to follow to process your images correctly. There are also several steps you should take to screen your photos for improprieties and security violations, which we will cover later in this chapter.

All the rules of basic photography still apply when it comes to shooting with a digital camera instead of an SLR camera. Framing, composition, lighting and the rule of thirds will always be the parameters that you will use to judge the value and the quality of the photographs you shoot.

The following sections address cropping photographs that will be scanned for insertion into your publication. Although the old method of cropping and scaling may seem outdated because of today's technology, it is still important for the staff journalist to know and understand the basic principles applied.

CROPPING

Cropping is used when you only want to reproduce a portion of a picture. Pictures are cropped for the size, emphasis and composition desired. They are also cropped to focus on one specific area to achieve a desired effect in makeup. A picture can be cropped to show the hugeness or smallness of the topic. It can also be cropped to delete a dead area.

Cropping Concerns

As a public affairs practitioner, your first responsibility is to make sure security, accuracy, propriety and policy are not violated when photographs are cropped. These areas are explained in the following text.

SECURITY.—During exercises, operations plans, maps, charts and equipment can be compromised easily by a photographer. Access is usually limited and photographers are kept away from secure areas, but breaches of security may occur in the heat of battle.

As you have heard before, "Operational security is everyone's business." When cropping a photograph for reproduction in your newspaper, you should be aware especially of the background areas that might reveal classified information. Remember—exercises test war plans, and those plans cannot be compromised.

ACCURACY.—Make sure the photograph reflects reality. A photograph taken from the wrong angle or at the wrong time can, in fact, misrepresent the facts of the story. A road race picture taken at the finish line can show the second place finisher ahead of the winner, if taken from the wrong angle. A sneeze or facial twitch during a somber ceremony can make the subject look like a fool in addition to misrepresenting the story.

PROPRIETY.—Beauty pageant swimsuit competitions, a Sailor in an embarrassing pose and ethnic misrepresentations are but a few of the many propriety violations you might face when cropping a

photograph. Although a photo editor should catch such violations during the process of photograph selection, you also must check for violations in the cropping phase.

POLICY.—Policy considerations are described, but are not limited to, the provisions of *PA Regs.* The DoD and DoN have release authority over certain types of information. Information on weapons systems, controversial national and international subjects and certain Navy contracts will have to be approved for release.

In overseas locations, local policies come into play. Photographs of antigovernment protests in your host country, for example, normally should not be taken in the first place. If you allow the photograph to be published in your newspaper, no matter how good your cropping job, you may enrage officials of the host country and your superiors. Policy considerations also include uniform violations, unsafe acts and promotional activities favoring one organization over another.

Distractions

Distractions come in the form of anything that takes the eye away from the center of interest and action taking place. It could be a spectator in the stands at a softball game or a student looking away from the instructor in a class. It could be anything that detracts from the purpose of the photograph. You must eliminate portions of a photograph that do not contribute to good composition.

When cropping photographs, narrow the cropped area to the center of interest as much as possible. The rule of thumb is to crop ruthlessly and enlarge generously.

Try to limit the number of people in the photograph to three, or only those necessary to tell the story. When cropping people, do not crop them at the neck, waist, knees or other joints.

Dead Space

To avoid unnecessary dead space in the photograph, you should keep the center of interest contained. However, in cropping out dead space, leave enough space to accommodate the action of the center of interest. For example, if a car is traveling to the left of the photograph, leave room on the left for the vehicle to travel. Do not cut it off at the front bumper. The car needs dead space in which to travel.

If the subject or center of interest in a photograph is looking to the right, you must allow enough dead space for him to look into. Be careful not to allow too much dead space in a photograph. Too much background may make the center of interest get lost or not stand out.

If you are working with a printed photograph, before scanning the image, the cropping marks are made at or near the corners of the photograph, as shown in figure 8-6. A china marker normally works best when making your cropping marks in the borders of photographs. China markers allow you to make changes without difficulty and mess.

Aesthetics

The aesthetics, or beauty of the photograph should be improved by cropping. The rule of thirds (fig. 8-7) suggests that the center of interest be positioned roughly at one of the four intersections created by equally spaced horizontal and vertical lines. These lines divide the photograph into horizontal and vertical thirds. When the subject is centered in the photograph, as is frequently done by amateur photographers, the photograph is often static and boring.

When you consider aesthetics, cropping should be based on the movement of the subject, leading lines, lines of force and other framing considerations that are explained in more detail in chapter 12.

Shapes

The shape of the photograph also must be considered before it is cropped. Normally, a 3:5 proportion is most pleasing to the eye. Proportions of 2:3, 3:4, 4:5, 4:7 and so on, are acceptable proportions. Simply cropping a photograph to make it square (3:3, for example) leaves a newspaper page dotted with square blocks and results in an unattractive page.

Figure 8-6.—Cropping marks on a photograph.

Figure 8-7.—The rule of thirds.

When you are considering the shape of a photograph, there are times when a strong vertical or horizontal will improve the look of a newspaper. Obvious examples where extreme horizontals and verticals work well include tall buildings, parades, travel photo features and many sporting events.

Photo Within a Photo

Careful examination of a print may allow you to extract two or more reproduction-quality photographs from a single print. There may be two centers of interest or separate actions taking place that separately qualify as photographs. In a football game, an offensive lineman may be blocking the star defensive end, while a wide receiver catches a short pass across the middle of the playing field. Both actions could be stand-alone photographs.

Cropping Methods

To manually crop a picture, you must mark off the unessential parts. This can be done by cutting, masking or using cropping L's.

CUTTING.—If the photograph or piece of artwork is expendable (you have several originals or the negative), you can do your cropping with a paper cutter. This is the most accurate method and the one most commonly used by ship and station newspaper editors.

MASKING.—When a section of a valuable photograph is to be reproduced, you may mask it by covering the picture face with a sheet of paper that has a window cut out to expose the desired area.

CROPPING L's.—Cropping L's (fig. 8-8) are useful tools when you are narrowing a photograph to its center of interest. Cropping L's are L-shaped cardboard or plastic devices, often black in color, used to eliminate dead space. When you place them over a photograph in the form of a rectangle, you can adjust them and see the effects of cropping before a crop is actually made.

Digital Cropping. —Using the cropping icon on your software editing program, highlight the area that you want the photograph to display. Your software program will ask you to set the size, style and format settings for your images and then automatically process them based on your input.

Photograph Dimensions

Before you can scale a photograph (explained later), you normally have to know the following three dimensions:

- Cropped width

Figure 8-8.—Cropping L's.

- Cropped depth
- Reproduction width or reproduction depth

CROPPED WIDTH (CW).—The cropped width is the width of the photograph, in picas, columns or a local unit of measurement, after cropping is completed. In the manual scaling of photographs and artwork, width is usually represented in picas, columns or the local unit of measurement. Width is not usually represented in inches because most other horizontal measurements in newspaper design are in picas, columns or a local unit of measurement (such as cicerós). In digital cropping, the width or height of your images may be measured in inches or in pixels. Using either method will require you to have a strong grasp and understanding of the photo or image software program you are using.

CROPPED DEPTH (CD).— The cropped depth is the depth of the photograph after cropping has been completed. Depth is usually represented in inches, **not** picas or columns.

REPRODUCTION WIDTH (RW).—The reproduction width is the actual width of the photograph for reproduction. This is the predetermined space allotted for the photograph before cropping or scaling takes place. The measurement usually is given by columns: two columns, three columns and so on. You must know the standard width of the column and alley and the space between the columns (one pica, one-eighth inch and so on) to get an accurate reproduction width.

You will use the three known dimensions (cropped width, cropped depth and reproduction width) to determine the unknown dimension, usually the reproductive depth.

REPRODUCTION DEPTH (RD).—The reproduction depth is the number of inches deep the photograph will be after enlarging or reducing it to fit in the space allotted for it on the newspaper page.

On occasion, you may set aside a vertical space to fill in your newspaper page design. In such a case, you are using the cropped width, cropped depth and reproduction depth to establish the unknown reproduction width. This reverse procedure is used frequently in photo layouts where standard column widths may not apply.

SCALING

Scaling is the act of either enlarging or reducing a cropped photograph or artwork to fit a hole on a

newspaper page. Since you must first know the cropped dimensions, you cannot scale a photograph before you crop it. Once you know the dimensions, then you can scale the photograph to fit that hole snugly.

In scaling a photograph, you are trying to determine either the reproduction depth or the reproduction width. As you enlarge or reduce the photograph to reproduction width, the reproduction depth will change proportionately. Consequently, when you scale for reproduction depth, the reproduction width will change proportionately.

It is important to note that scaling photographs or images on a computer makes all the difference in the world of the quality of photographs or images you will have. Images should be reduced or enlarged before inserting them into your publication. This will maintain the proper settings of the image. Resizing images after they are inserted into your publication could result in distorted, out-of-focus or unproportional images in your publication.

When scaling digital images, you will need to use a software program that is not only one you can understand, but also one fully compatible with your publication's desktop software program.

Images can be cropped and scaled in a matter of minutes using digital software, but the basic rules of photography still apply. A good rule to remember is "Crop first, then insert." This will ensure that the final image product is the same as the one you ended up with when you cropped (or scaled) it back at the office.

The two simple manual ways to scale a photograph or artwork to size are as follows:

- The diagonal method
- The proportional scale method

The Diagonal Method

The diagonal method of scaling a photograph or artwork is a mechanical procedure that does not require great mathematical skill or special tools. Diagonally scaling for reduction (fig. 8-9) includes five steps as follows:

1. On a separate sheet of paper, draw a rectangle that has the same dimensions as the **cropped** photograph/artwork.
2. Draw a diagonal line from the lower-left corner through the upper-right corner of the rectangle.

Figure 8-9.—Scaling for reduction.

3. Measure from the lower-left corner, along the baseline, the width desired for the picture. Make the baseline extend to that point.

4. Draw a broken vertical line at a right angle from it to the diagonal line. Stop where the broken line and diagonal line intersect.

5. Complete the rectangle and measure the space. This is the area your photograph will occupy when it is reduced.

Diagonally scaling for enlargement (fig. 8-10) is slightly different from the procedure used for reduction. It contains the following five steps:

1. On a separate sheet of paper, draw a rectangle that has the same dimensions as the **cropped** photograph/ artwork.

2. Draw a diagonal line from the lower-left corner through the upper-right corner of the rectangle.

3. Extend the baseline with a broken line to the width desired for the picture.

4. Draw a broken vertical line at a right angle from it to the diagonal line as before. Extend the diagonal line to meet the broken line.

5. Complete the rectangle and measure the space. This is the area your photograph will occupy when it is enlarged.

The Proportional Scale Method

Perhaps the most common way of scaling is the proportional scale method. The proportional scale (fig. 8-11) has a movable inner disk with a window

Figure 8-10.—Scaling for enlargement.

mounted on an outer disk. Both disks have unit graduations from 1 to 100. Any unit of measurement can be used with the proportional scale.

To use the scale, you need to know three of the four measurements involved in scaling. You must know the cropped width, cropped depth and reproduction width (or the reproduction depth if you are establishing a reproduction width).

Use your proportional scale to determine the reproduction depth in the following example:

PHOTOGRAPH DIMENSIONS: The cropped width is 5 inches and the cropped depth is 2.5 inches. It will be used in a one-column, 13.5 pica-wide space.

STEP 1: Align the cropped width (5 inches) on the **inner** disk, with the reproduction width (2 inches) on the outer disk.

STEP 2: Find the cropped depth (4 inches) on the **inner** disk and read the reproduction depth opposite it on the **outer** disk. The reproduction depth is 2 inches.

The window on the inner disk displays the “percentage of original size.” In the preceding example, the photograph will be reduced to 50 percent of the cropped size. Percentages less than 100 indicate a reduced size; those higher than 100 mean the photograph will be enlarged. If you work for a CE or funded newspaper, your printing contract may stipulate maximum reduction and enlargement percentages and sizes.

Marking Photographs

Photographs or other artwork must be marked appropriately so the publisher will know exactly what you want. Instructions are usually printed on the reverse of a photograph with a china marker. For instance, you mark a photograph “1-A, reduce to 24 picas by 5 inches” (width is always given first in art sizes). The “1-A” is a way of letting the publisher know you want the photograph to appear on page 1, fitted into a space designated “A” on the layout. It also tells the publisher that you have scaled the photograph, and when reproduced, it will occupy a space 24 picas

Figure 8-11.— Proportional scale.

wide and 5 inches deep; or you might simply use slugs to match a story with a related head, art and outline. Usually, an editor devises the “key” system to be used.

TYPOGRAPHY

Typography is the art of printing with type. It involves the style, arrangement and appearance of the printed page. As editor of a ship or station newspaper, you should be familiar with a few important type-related terms.

Printers’ Measurements

Type size is measured in **points**. One point is approximately one seventy-second of an inch. Twelve points equal one pica (remember—six picas equal one inch). Points are used to measure the height of a letter of type. The width of a line of type is given in picas. Most newspaper columns are about 12 picas (2 inches) wide. Type ranges in size from 3 to 120 points. Your stories will usually be printed in 8- or 10-point type. Most of your headlines will range from 12 to 36 points. The depth of a column of type or art (measured down the page) is given in inches. A **column inch** is one column wide and 1 inch deep; a photograph two columns wide and 3 inches deep occupies six column inches.

This method of measuring copy is still used today throughout the newspaper industry despite the use of desktop publishing software. All newspaper editors should know how to measure copy, and the various type (or font) families available for use in their publications.

Type Classification

Did you ever stop to think how many different kinds of handwriting you come across in a single day? Some are large and bold, some are weak, some small, some clear and some are almost illegible. Type styles, called **typefaces**, are much the same.

The first concern of selecting a type is, of course, clarity. Type must be legible. However, there is more to it than that. Like handwriting, typefaces reflect certain characteristics, such as refinement, dignity, boldness or strength. Properly used, they can convey the feeling or mood of a message. They may be warm, brisk, dignified, modern or old-fashioned—whatever is needed to emphasize or suggest the thoughts expressed in copy.

Type can be used to attract the reader’s attention. The use of large boldfaces is one of the most effective ways of stopping the eye. Large, boldface type, however, is difficult to read. It should be limited to a few words and should be followed by smaller, more legible typefaces that invite reading.

Most kinds of type have both capitals and small letters. Publishers use the term **uppercase** for capitals and **lowercase** for small letters. These terms originated in early printshops where type was set by hand. The less-used capital letters were stored in an upper storage case and the frequently-used small letters in a lower one.

As early as the seventeenth century, publishers knew they had to organize their typefaces efficiently. They arranged their typefaces into main type classes. The six main classes of type (fig. 8-12) are as follows:

- Roman
- Gothic
- Text
- Italics
- Script
- Contemporary

ROMAN.—Roman is the type most commonly used for the text of magazines, newspapers and books. It is chosen because most readers are familiar with it and because it is the easiest to read in smaller sizes and in lengthy articles.

Roman types are divided into two classifications: **modern** and **old style**. The chief difference between modern and old style roman is found in the serifs (the small cross strokes at the ends of the main lines of a

Figure 8-12.—The six main classes of type.

letter). The old style letter has soft, rounded serifs, while the modern letter has heavier shadings and thin, clean-cut hairlines.

GOTHIC.— Study the difference between the roman letter and the gothic letter in figure 8-12. You will notice that where the roman letter is composed of a series of thick and thin lines, the gothic letter is constructed of lines of even weight. It has no serifs (known in the printing profession as “sans serif”); it is perfectly plain. Gothic type is popular for use on posters and as headlines.

TEXT.— Text type is sometimes referred to as “Old English.” Text was the first type style used in the history of printing. Although it is still used frequently, it is generally limited to a few lines of copy. As far as newspaper work is concerned, it should be limited to something formal, such as religious announcements, prayers, programs and invitations.

ITALIC.—In italic type, the letters are slanted and made to match almost every roman, gothic and contemporary type style in use today. Italic is used in text matter to show emphasis. Although italic was originally used for text, it was rather hard to read in lengthy articles and it is seldom used for this purpose today.

SCRIPT.—Script typefaces have little connecting links, or kerns, that combine the letters and give them the appearance of handwriting. Script is suitable for announcements and invitations.

CONTEMPORARY.—The past 50 years have been highly significant in typographic history. The old gothics have had their faces lifted, and new streamlined faces have appeared everywhere. Contemporary type refers to the thousands of modern, artistic faces used in a variety of ways, such as advertisements, labels on cans and boxes, display composition and television commercials. The example of contemporary type shown in figure 8-12 is bold (heavy block), but the same group contains lightface letters. In general, modern types feature more lightfaces than bold.

Type Families

From classes, type is further categorized into typefaces that are similar in design, though not exactly alike. These groups are called type families. Each type family has a name and a certain basic family resemblance. Many type families are named for their creators, such as Bodoni and Goudy. Some names come from regions or nations: Caledonia and Old

English. Some type families include dozens of typefaces, all different in some way, yet all having general characteristics that unmistakably identify them as members of their particular family, such as the Bodoni family in figure 8-13.

Type Series

The next type category refers to the weight, width and angle of type. This category is called type series. When a series carries only the family name, with no adjectives indicating variations in width, weight or angle, assume that the type is normal. The usual distinction is between big letters (called display or headline type) and small letters (called body or text type).

Type Font

Type font is the next category and has all the letters, numbers and characters necessary to set copy in one size of type. However, a modern newspaper uses

Figure 8-13.—Various typefaces in the Bodoni family.

either one or two families of compatible type to achieve variety in the series choice and point size.

INITIAL LETTERS

Initial letters are large, ornate, capital letters that are sometimes used at the beginning of a paragraph to dress up the page and add white space. They come in all sorts of styles. When an initial letter is used, the remainder of the word it begins with is generally capitalized. You may use either regular capital letters or slightly smaller capital letters of the same style of type.

ORNAMENTS

Ornaments, such as stars (called “dingbats” in publisher’s lingo) and dots (called “bullets”), are used to add interest and beauty to a job. When using ornaments, you should always select something that goes well with the style of type you are using. Above all, do not overdo them. Fancy types and decorations should be used only if they make your newspaper page more effective. Decoration, just for decoration’s sake, was abandoned at the turn of the century in favor of simple harmony and balance.

BORDERS

You should select borders and layout lines with the same care you use to select a typeface, because the same general principles of typography apply. Figure 8-14 shows some typical ornaments and borders.

A study of type size and classifications could take up an entire book. The basics presented here will help you both in preparing an attractive publication and in conversing with the publisher. For all practical purposes, all you have to know is the answer to the question, “What kind of type is available to me?” A trip to your publisher or local printshop will give you that answer.

NEWSPAPER MAKEUP

LEARNING OBJECTIVE: *Recognize the objectives of a ship or station newspaper makeup and the techniques used to meet them.*

“Newspaper makeup” is defined as the design of a newspaper page or the manner in which pictures, headlines and news stories are arranged on a page. The objectives of newspaper makeup are as follows:

Figure 8-14.—Ornaments, borders and dingbats.

- To indicate the importance of the news
- To make the page easy to read
- To make the page attractive

FRONT-PAGE FOCAL POINT

Each page of a newspaper has a focal point —a point on the page to which the reader normally looks for the most important story. Any area can be the focal point, depending on the chosen design. Advertisements can also dictate the focal points of the inside pages of a newspaper.

On the front page of some daily newspapers, the focal point is often in the upper right-hand corner, a now-dated practice that reflects the style of a bygone era. Americans, although trained to read from left to right and top to bottom, greatly altered this pattern for many years with respect to their newspaper reading habits. Through the use of banner headlines that extended more than half the width of the page, readers were trained to seek the upper right-hand corner of the front page. Newspaper readers begin their reading by following the banner headline across the page and continuing down the right-hand side of the page. Therefore, many newspaper readers have come to expect the most important story in each issue to appear or touch in the upper right-hand corner of the front page.

The right-hand focal point is not as important to makeup editors as in the past, since fewer newspapers use banner headlines on the lead story. However, many newspapers still carry the most important story in the upper right-hand corner of the front page because of established practices.

Today, a large percentage of newspaper editors use the upper left-hand corner as the focal point. These editors think that readers, trained in school to read other literature from left to right, prefer their newspapers to be designed that way, too. A few editors

still use other areas, such as the upper center of the front page as the focal point. Only time will tell which is best, if indeed, there is a “best.”

INSIDE PAGE FOCAL POINT

The focal point on inside pages is the upper left-hand corner if there are no advertisements. Therefore, the focal point is influenced by a newspaper reader’s natural sight tendencies and is not hampered by customs.

On inside pages with advertising, the way ads are placed on the page influences the position of the focal point. The focal point is always opposite the lower corner of the page that is anchored by the largest mass of advertising.

MAKEUP LINES

You will use the following four basic types of “lines” in newspaper makeup:

- Vertical
- Diagonal
- Circular
- Horizontal

Vertical Line

The vertical line is used to get the reader to read up and down the page. The line is carried out on the page by displaying stories, headlines and pictures vertically on the page. It is characteristic of the makeup of newspapers in early America and is still used to a limited degree in making up newspapers today.

Diagonal Line

The diagonal line is used in newspaper makeup to get the reader to read through the page. The line is carried out on the page by displaying headlines and pictures so together they form a diagonal line from the upper left-hand corner to the lower right-hand corner of the page. Also, a page can contain a double diagonal by forming another diagonal in the opposite direction from the first. The diagonal line lends a sense of rhythm to the page. It is characteristic of many of today’s newspapers.

Circular Line

The circular line is used in newspaper makeup in an attempt to get the reader to read around the page. The line is carried out on the page by displaying stories, headlines and pictures on the page so the reader sees each as being equally important. This creates a tendency on the reader’s part to read all the stories. The circular line is used to a limited degree in modern newspapers.

Horizontal Line

The horizontal line is used in newspaper makeup to get the reader to read back and forth on the page. The line is carried out by displaying stories, headlines and pictures horizontally on the page. The horizontal line is a post-World War II development and it is probably the most striking change in the appearance of newspapers in this century. It is a characteristic of many present-day newspapers.

NEWSPAPER DESIGN CONCEPTS

LEARNING OBJECTIVE: *Recall the design concepts used in ship or station newspaper makeup.*

Successfully designing a newspaper page encompasses more than experimentation. It is actually a calculated art evidenced by the following five newspaper design concepts:

- Balance
- Contrast
- Rhythm
- Unity
- Harmony

BALANCE

In the balance concept, the page designer (hereafter referred to as the editor, although it may be any member of the newspaper staff performing this function) tries to balance heads against heads, pictures against pictures, stories against stories and artwork against artwork. This balance, however, is a relative balance, and it is not measurable but is something gauged in the viewer’s mind. Therefore, the editor has to sense, rather than measure, the balance for a page. This perception is one developed by experience. The editor looks at the page as a whole and tries to achieve a

relative balance in either the horizontal or vertical halves of the page.

CONTRAST

In the contrast concept, the editor strives to separate display items on the page so each gets the attention it deserves. The editor uses type, headlines, pictures, white space and color to achieve contrast.

For example, the editor can achieve contrast with type by using regular type with boldface type. Headlines also can be contrasted by using bold, black heads or by displaying roman type with italic type. The editor can achieve contrast with pictures by using verticals with horizontals, small column widths with large column widths or dark and light photographs. Further, the editor can achieve contrast through color by displaying black type with color boxes, pictures and heads.

RHYTHM

By using the rhythm concept, the editor tries to get the reader to move from one element to another element on the page. Rhythm is achieved in newspaper makeup by staggering headlines, stories and pictures on the page.

UNITY

The unity concept of newspaper makeup is used to tie the page together; therefore, the page is not divided into one, two or more sections.

A page that lacks unity is called a paneled page. You can avoid paneled pages by crossing the column gutters (space between columns) with headlines and pictures in the middle areas of the page.

HARMONY

The harmony concept is used to give a newspaper a standard appearance from day to day. Harmony generally refers to typographic harmony. This means using one typeface for body type and a contrasting typeface for cutlines. Headlines should have the same typeface as the body type and may be varied by weight and the use of italics on occasion.

ELEMENTS OF NEWSPAPER MAKEUP

LEARNING OBJECTIVE: *Identify the individual elements used in ship or station newspaper makeup.*

Thus far, all the subject matter in this chapter has dealt with the tools and materials available for presenting the reader of a ship or station newspaper with an attractive, interesting and convenient look at the news. Whether you achieve the desired product will depend on how these tools and materials are used in assembling your newspaper.

If you are the person responsible for laying out, making up or actually pasting up your newspaper, you should adopt a basic typographic plan or style. First, read all of the copy being considered for the newspaper. Study the pictures and other artwork closely. Visualize the news story message or ideas, and the nature of the artwork as a whole. Decide the relative importance of the elements; then put the entire page together using the individual components of newspaper makeup (fig. 8-15).

Makeup creates recognition of a newspaper. A good editor varies the makeup in each issue, so the readers are not bored with the newspaper. On the other hand, each page will resemble the previous editions enough so the reader can immediately identify it.

The following components help the reader identify a newspaper:

- Nameplate
- Flags
- Masthead
- Headlines
- Pictures
- White, gray and black
- Rules

NAMEPLATE

The nameplate should be simple in design, attractive and in harmony with the character of the paper. Its type should either harmonize or contrast with the headline type. The nameplate can combine type and artwork together. The artwork, however, should not make the nameplate jumbled and hard to read. Figure 8-16 shows several examples of nameplates.

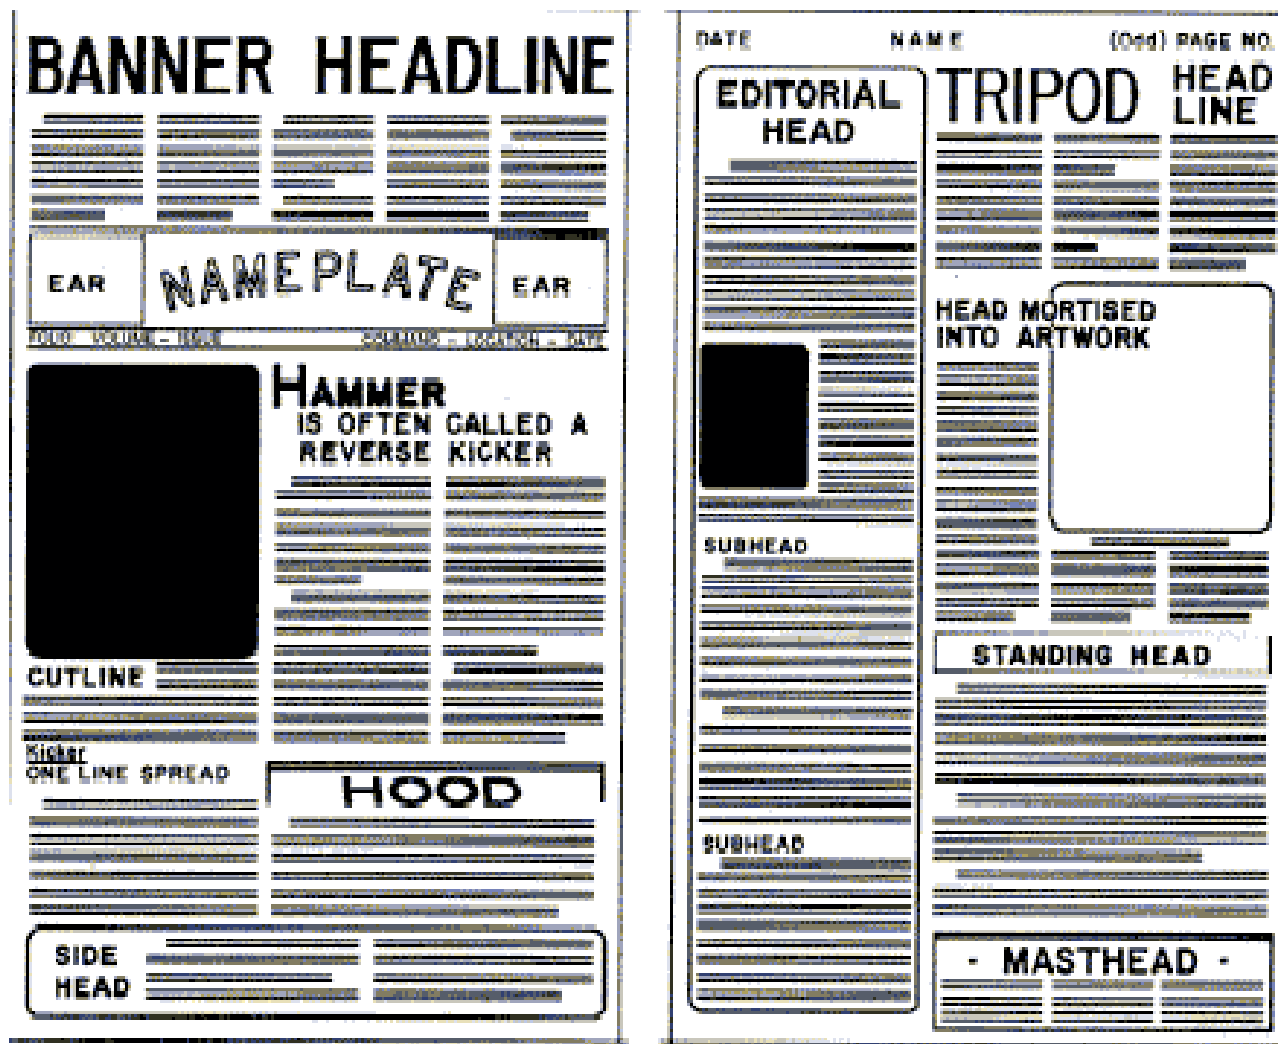

Figure 8-15.—Individual components of newspaper makeup.

The nameplate can be made to float on the page. Although a nameplate that runs the entire width of the page can be made to float, a floating nameplate usually occupies two or three columns and is placed anywhere in the upper third of the page.

FLAGS

A flag of the newspaper is a display used by a newspaper to indicate section pages or special pages, such as editorial, sports and family pages. Just like nameplates, a flag should not dominate its page and should appear above the fold. Flags can also be floated. (NOTE: Some authorities maintain that a flag is the same as a nameplate and identifies a section head as a “section logo.” We do not.)

MASTHEAD

A masthead of the newspaper is often referred to, incorrectly, as a nameplate. A masthead is a statement

that should appear in every edition to give information about the publication.

The masthead of a CE or funded military newspaper includes the following elements:

- The name of the officer in command or head of the activity.
- The name of the newspaper and the producing command.
- The following statement: “The editorial content of this newspaper is prepared, edited and provided by the public affairs office of (command).”
- The name, rank or rate (if military) and editorial position on the newspaper staff or all personnel assigned newspaper production and editing duties. This is listed under the heading “(command) Editorial Staff.”

Figure 8-16.—Newspaper nameplates.

- The following disclaimer: “This newspaper is an authorized publication for members of the military services (add the words ”stationed overseas,” “at sea” or “and their families” if applicable). Its contents do not necessarily reflect the official views of the U.S. Government, the Department of Defense or the U.S. Navy and do not imply endorsement thereof.”
 - The following disclaimer (for CE newspapers only): “The appearance of advertising in this newspaper, including inserts of supplements, does not constitute endorsement by the Department of Defense, the U.S. Navy, (name of command) or (name of publisher) of the products and services advertised.”
 - “Everything advertised in this newspaper shall be made available for purchase, use or patronage without regard to race, color, religion, gender, national origin, age, marital status, physical handicap, political affiliation or any other nonmerit factor of the purchaser, user or patron. If a violation or rejection of this equal opportunity policy by an advertiser is confirmed, the publisher shall refuse to print advertising from that source until the violation is corrected.”
 - “Published by (name of publisher), a private firm in no way connected with the DoD or U.S. Navy, under exclusive contract with the U.S. Navy.”
- For second-class mailing, postal regulations require a masthead to be within the first five pages of the newspaper. These regulations also require that the masthead contain the following information:
- Name of publication
 - Date of issue
 - Frequency of publication
 - Issue number
 - Subscription price (if applicable)
 - Name and address of the publisher
 - Second-class mailing imprint
- The masthead of CE or funded newspapers must be printed in type not smaller than six point. Additional information on mastheads may be found in *PA Regs* or *Ship or Station Newspaper/Civilian Enterprise (CE) Publications*, NAVPUBINST 5600.42.

HEADLINES

Headlines, or simply heads, contribute to all five concepts of newspaper design —balance, contrast, rhythm, unity and harmony.

The headline for one story should be separated from that of another. Heads that appear side by side (called “tombstones”) could be read as one head and confuse the reader. Tombstoning also prevents each head from gaining its share of attention.

When headlines and pictures are used together, they should be placed so the reader is not confused by their positions. You should not place a picture between a headline and a story, because the reader might begin reading the cutline thinking it is the first paragraph of the story.

Heads of the same column width should not be placed lower on the page than a smaller one, or higher on the page than a larger one. This does not mean that the bottom of the page cannot contain a large multicolumn head. It only means that heads of the same width should decrease in point size as they descend the page.

Do not run stories out from under their heads. This creates a readability problem by confusing the reader about where to find and finish reading the rest of the story.

A story can be wrapped (to continue a story from one column to the next) under its main head, or lead, to achieve variation. A story is always turned to the right from its main part. A turn running above the headline of the story could confuse the reader and cause the individual to abandon the item.

A story requiring a “jump,” or continuation, to another page should be split in midsentence, never at a period of a paragraph.

For example, “(Continued on page __, col. __)” will direct the reader adequately. The jumped portion should carry a brief head, or key word, taken from the main head to identify it as a continuation. The “jump head” should be keyed to the same type style and face, although it seldom will be in the same type size, as the original headline. Never jump a story on a hyphenated word, or carry over the last line of a paragraph.

PICTURES AND IMAGES

Readability studies have shown that pictures (images) are one of the most popular elements in a

newspaper. For that reason alone, important images should be large and positioned in a manner that maximizes their display.

Images of two-column widths or more should be placed on a page so they stand or hang from something that gives them support. An image can stand on a headline, another picture or the bottom of the page. Images can hang from a headline, another image or the top of the page. An image of two-column widths or more should not float in copy, but a one-column-wide picture or smaller can float in copy.

Images and headlines that are not related should be separated by more than a rule, if the possibility exists that, when placed together, they are humorous or in bad taste.

Avoid any clashing items. For example, do not place an accident story next to a mortuary advertisement. (Discuss the placement of advertisements with your editor or the CE newspaper publisher.)

If you run two photos, two boxes or a photo and a box side by side, except in cases where the subjects are related, they tend to cancel each other out. It is best to separate unrelated artwork with body type.

Reader’s eyes have a tendency to follow the line of sight of people in pictures. Therefore, if people in a picture look off the page, readers will tend to look off the page. To prevent the reader from doing this, the main subjects in pictures should look straight ahead or into the page. This also holds true for pictures showing action. The motion should go toward the center of the page whenever possible. This reader tendency can be used to your advantage. The line of sight and motion can be used to guide the reader’s eye through a page.

Try to avoid running images on the horizontal fold of a newspaper, because the area along the fold becomes distorted once the newspaper has been folded.

Do not give a photograph more display space than it deserves, especially a “mug shot” (portrait-type, close-up photograph of an individual). Mug shots can float in copy, but it is best if they stand on or hang from something. If a mug shot floats, it is best to float it within a sentence in a paragraph. Mug shots should be accompanied by at least a name line for identification. By omitting the name line, the reader is forced into trying to identify the individual in the picture.

“Thumbnails” also are used in making up newspaper pages. The term refers to half-column mug

shots. A thumbnail is best used when it looks into the story or directly out of the page. A name line, in most cases, should also be used with thumbnails.

WHITE, GRAY AND BLACK

A newspaper page is made up of varying degrees of white, gray, and black. Some pages may contain other colors. A good editor strives for relative balance of colors on a page and will not let any color dominate the page. You will not have any problems with white pages, black pages or any other colored pages; your concern is staying away from gray pages.

There are many ways to relieve grayness, or gray-out, which is created by large areas of body type. One way is to use multicolumn images to break up columns of type. Another way is to use thumbnail images.

Type also can be used effectively to relieve grayness. To break up gray areas in a long story, you can set selected paragraphs in boldface type, if used sparingly. Another method of breaking up long gray stories is to use boldface subheads set about two points larger than your body type size. A third method of using type to break up grayness is to use boldface, all-cap lead-ins. This method is particularly effective in matter set in wider measures. In two-column matter, the first three to five words of the paragraph containing a lead-in can be set in boldface and all caps, and in one-column matter, the first one to three words of the paragraph can be set in boldface and all caps.

The paragraphs to be set in any of these boldfaced methods should be the paragraphs that introduce a new element into the story or ones that contain information of more than usual interest. Two paragraphs using the same boldfaced method should not be run side by side because they tend to cancel each other out. Note that the use of boldface type is not favored by the editors of contemporary newspapers as much as by the editors with traditional leanings. (More about traditional and contemporary designs will be presented later in this chapter.) “Modern” editors rely on the use of different design concepts to eliminate large gray areas on their pages and, consequently, have little use for boldface type, except possibly as subheads.

Other useful devices in breaking up grayness are initial letters (mentioned earlier in this chapter), kickers, and hammerheads (covered in chapter 9) and sandwiches.

A sandwich is a device for handling “reefers” (references to a related story on another page). It is a small, sideless box made with the same rule used for regular boxes. The reefer type in the sandwich should be set in boldface and not be indented. No headline is needed and it should be brief, containing not more than two or three lines.

The sandwich should be placed about 2 1/2 inches deep into the story. Presumably, this practice gives the reader enough time to become interested enough in the subject being addressed to want the related information being offered. The use of the sandwich assumes the reader will immediately turn to the related story, read it, and then return to the original story and continue reading below the sandwich.

Special effects can be obtained with special art, such as boxes and ornaments (art borders around individual stories, announcements and ads or the entire page). These devices are also effective gray breakers but should be used sparingly, so their use does not create a cluttered effect. In using boxes, you can indent a story on all sides and use a box of white space all around the story. You can also indent on all sides of a story and then use a ruled box. Dingbats, once in vogue, are now considered old-fashioned and are shunned by modern editors. White space provides margins to frame your page. Side margins should be the same width, but bottom margins should be about one-fourth wider than your top margins to give your page a lifted look. White space is also used to give breathing room around headlines and pictures in much the same manner as margins frame the page. However, you should make an effort to avoid the appearance of trapped white space. White space should run to the outside of the page.

RULES

Rules are commonly used typographic devices in newspaper makeup. Properly used, they separate unrelated items and unite related ones. The two types of rules used are the column rule and the cutoff rule.

Column Rule

The column rule is a vertical, thin line that runs from the top to the bottom of a newspaper page. Use the column rule to separate columns of type and to separate unrelated items, such as photographs and stories, from the rest of the page. Part of a column can be deleted to indicate that the items joined are related.

Cutoff Rule

A cutoff rule is a horizontal, thin line that runs across one or more columns of a newspaper page, depending on the width of the items to be separated or united. A cutoff rule is used to separate unrelated items, such as boxes, photographs, multicolumn headlines, and advertisements from the rest of the page. A cutoff rule helps the reader's eye turn the corner from where a story ends in one column to where it begins in the next column, except when the story wraps from the bottom of a page; then no cutoff rule is needed.

ADDITIONAL MAKEUP CONSIDERATIONS

Newspapers have other elements that usually appear in each issue and other makeup devices that are used to design newspaper pages. Some of these are described in the following text.

Widows

Avoid having widows at the tops of columns. A widow is an incomplete line, as one that ends a paragraph. When there is a widow, carry two lines to the new column or page.

Wrapping Copy

When you wrap copy, wrap at least 1 inch of copy into the next column. That is approximately six lines of type. Studies have shown that anything less than an inch of copy lacks eye appeal.

When you wrap a story, split paragraphs at the bottom of the column, when possible, to indicate to the reader that the story continues in the next column.

Folio Line

A folio line is an identification line of the newspaper on each page. The folio line on the front page is different from those on inside pages, as described in the following sections.

FRONT-PAGE FOLIO LINE.—A front-page folio line joins the nameplate and consists of the volume number (the number of years the publication has been in print), the issue number (the number of issues published within the present year), command, location (city and state) and date of publication. It does not carry a page number and is usually separated from

the flag by a border and a cutoff rule or by two cutoff rules.

INSIDE PAGE FOLIO LINE.—An inside page folio line generally runs at the top of each page. It also can run as part of a flag that appears on special pages or within the masthead on the editorial page. The inside page folio line consists of the publication date (left corner of the page), name of the newspaper (centered) and the page number (right corner of the page). An inside page folio line is normally separated from the rest of the page by a cutoff rule, but as you can see in figure 8-15, this is not a requirement.

PAGE PERSONALITY

The quality of the layout and makeup of the inside pages of your newspaper should receive the same attention as the front page of the newspaper. Readers should not be shortchanged once they leave the front page of a newspaper. Special pages, such as editorial, family and sports, should have their own personalities.

Editorial Page

The editorial page probably is the least read of all the inside pages. The reason can be attributed particularly to makeup. Most editorial pages are very dull and very gray. A good editorial page should be as different in makeup from other inside pages as possible. Use pictures and artwork, white space, odd-column sets and other elements of makeup to give the editorial page its own special traits.

Family/Leisure Page

An appealing family/leisure page features delicate type, white space, and artistic designs. Use large and dramatic pictures to complement articles on off-duty leisure activities.

Sports Page

An attractive sports page contains plenty of action pictures. Be sure to include masculine type, white space, odd-column sets and large, bold headlines to complement the flavor of this popular newspaper page.

Other Pages

Inside news and feature pages should be as attractive as front pages within the limitation of available space. Use pictures, white space,

multicolumn heads, artistic designs and groupings of related news and features on these pages.

PICTURE STORY LAYOUT

LEARNING OBJECTIVE: *Identify the main points of a picture story layout.*

The picture story layout (also addressed in chapter 12) is a special challenge to a layout editor. A good picture story is a logical, well-organized, self-contained unit in which each part has a specific function.

The format used to lay out the picture story depends on space limitations and what you, as the layout artist, consider the most attractive arrangement. With an imaginative photographer, the number of interesting picture stories your publication can produce are unlimited. Once you have been provided with a variety of interesting, action-packed pictures suitable for reproduction, the layout is up to you. Let your experience and good judgment be your guide in determining the arrangement of pictures, headlines, cutlines, text and borders.

A good picture story layout (fig. 8-17, 8-18 and 8-19) can add immeasurably to the interest and attractiveness of your publication. Like feature stories, picture stories can be made up in advance and used as either regular attractions or to spice up occasional issues.

In the following text, we cover the major points of assembling a picture story.

NUMBER OF PICTURES

The number of pictures required to make up a picture story depends on the importance and

complexity of the subject. However, an odd number of photographs should be used in a double-truck layout. The term *double truck*, also called a centerfold, is used for a two-page layout made up as one page, with the “gutter,” or normal margin between the two pages, eliminated.

LEAD AND LAST PICTURE

The most important picture of any picture story is the one that opens the story —the lead picture. This picture has a double function. First, it must attract the reader’s attention and make that person want to know more about the subject. For that reason it should be the largest in your picture story. Second, it must show the subject and theme of the story in a graphically interesting form.

Almost as important as the lead picture is the last picture. The closing picture should show the reader the significance of the subject to the story line or theme.

BODY OF THE STORY

The body, which shows important scenes of the subject in action, must be varied and lively in visual rendition and presentation. To provide this variety and liveliness in a story, the photographer should start with a good script, excellent change of pace in coverage techniques and a quick eye for unexpected developments during actual shooting. By careful study of major picture magazines, photographers, as well as layout artists, you can gain a great deal of insight into the type of pictures being used in picture story assignments.

Figure 8-17.—Picture story layout, PT I.

Figure 8-18.—Picture story layout, PT II.

Figure 8-19.—Picture story layout, PT III.

PICTURE DIRECTION

Some photographs, because of their compositional direction, are natural right-hand or left-hand photographs. This means that the photograph is a natural to be used on the right or left side of a page, photo display or picture layout. Picture stories are viewed in the same manner in which we read, from left to right. Therefore, the lead photograph should be one that has the subject facing toward the viewer's right and the ending photograph facing toward the viewer's left. When possible, all lead and ending photographs should be taken twice: once with a left-hand direction and again with a right-hand direction. By duplicating these shots, you provide flexibility for layout. All photographs have direction: left, right, upward, downward, straight in or straight out of the page.

HEADLINES, CUTLINES AND TEXT

Headlines, cutlines and text have double functions. First, they give the reader facts that supplement the pictures editorially. Second, they serve graphically as elements of composition that contribute to the organization of the picture story.

PROOFREADING

LEARNING OBJECTIVE: *Identify the purpose of proofreading newspaper galley proofs and recognize the standard proofreader's marks.*

Proofreading is one of the final steps in the printing process (from the standpoint of the JO, not the publisher).

After the publisher has typeset your copy, you will receive the initial copies of your typeset stories. These copies are called "galley proofs," "galleys" or just plain "proofs." The galley proof name originated in the printing profession many years ago. Proofs of long rows of type came direct from the "galleys," or trays, in which the type sits until makeup time at the printshop.

WORKING WITH GALLEY PROOFS

Your job is to read through the galley proofs—every word and every punctuation mark—to make sure there are no errors and that they conform to the original copy. If an error is found, it will be corrected at the expense of the publisher (in a commercial printshop). However, the cost of any changes in the original copy must be borne by your

command, since they result in extra work for the publisher.

In photo-offset printing, you are likely to be given the complete paste-ups of pages (publisher's reproducible, sometimes called reprints) for proofreading. Proofreading is usually done by all members of the newspaper staff and printshop personnel. The reason is obvious; checking the content of your publication is part of your job.

PROOFREADER'S MARKS

Proofreader's marks (fig. 8-20) and copy editing marks are, for practical purposes, the same. The main difference is in their usage.

There are two popular methods of noting proofreader's marks on galley proofs: the "book" and "guideline" systems. Both systems are covered in the following text.

Figure 8-21.—Proofreader's marks using the book system.

Book System

In using the book system (fig. 8-21), you make two marks to correct each error: one under the error and one in the margin. Place a caret (^) under the error. In the margin, place the appropriate proofreading symbol level with the line in which the error occurs.

Figure 8-22.—Proofreader's marks using the guideline system.

PROOFREADER'S MARKS	
○ Insert period	Cap. Caps—used in margin
^ Insert comma	≡ Caps—used in text
:	Cap. & small caps—used in margin
;	≡ Caps & small caps—used in text
? Insert question mark	lc. Lower case—used in margin
! Insert exclamation mark	/ Lower case—used in text
/ Insert hyphen	wf. Wrong font
↓ Insert apostrophe	○ Close up
⌘ Insert quotation marks	⌘ Delete
— Insert 1-en dash	⌘ Close up and delete
— Insert 1-em dash	⌘ Correct the position
# Insert space	⌘ Move right
⌘ Insert lead	⌘ Move left
~ Insert virgule	⌘ Move up
✓ Superior	⌘ Move down
^ Inferior	Align vertically
(/) Parentheses	≡ Align horizontally
[] Brackets	⌘ Center horizontally
□ Indent 1-em	⌘ Center vertically
□ Indent 2-em	↓ Push down space
¶ Paragraph	~ Use ligature
No ¶ No paragraph	⌘ Equalize space—used in margin
tr Transpose—used in margin	~ Equalize space—used in text
tr Transpose—used in text	✓ Decrease space
sp Spell out	⌘ Let it stand—used in margin
ital Italic—used in margin Let it stand—used in text
— Italic—used in text	⌘ Dirty or broken letter
bf Boldface—used in margin	run over Carry over to next line
~ Boldface—used in text	run back Carry back to preceding line
sc. Small caps—used in margin	Copy out Something omitted—see copy
≡ Small caps—used in text	⌘ Question to author
rom. Roman type	^ Caret—General indicator used to mark exact position of error in text.

Figure 8-20—Standard proofreader's marks.

Guideline System

In the guideline system (fig. 8-22), you place the appropriate proofreading symbol in the margin and draw a line from it to the error. This is the most common form of using proofreader's marks.

Check with your editor or associate editor to see which proofreading method is preferred.

WHAT HAPPENS AFTER PROOFREADING

After the corrections have been made and you have approved the galley proofs, the publisher takes and assembles type, along with photographs and other art, into pages according to the layout plan you submitted. From these, the publisher makes page proofs—and usually gives you a final chance to make sure there are no errors. Make sure headlines are with the proper stories, stories “jump” to the correct pages, paragraphs are in proper sequence and cutlines are under the correct photographs. Check the body type, too. Sometimes a slug gets misplaced or jumbled, but routine typesetting errors should have been caught long before you reach this point. You will make a permanent enemy of the publisher if you start making unnecessary alterations.

After the final proofs are reviewed and approved, the publisher produces a “blueline” version of the newspaper for the editor to review. The blueline is a replica of the newspaper in reverse and is comparable to a blueprint. After the blueline is approved by the editor, the newspaper is published and distributed. Additional information on the blueline can be found in the *JO 1 & C*.

If you work on a newspaper staff, you will do a lot of proofreading. For this reason, you should ask for a tour of the newspaper printing plant. Observing the printshop in operation makes you more aware of the publisher's problems than you might otherwise see and helps you give clearer, more useful directions for what you want on the galley proofs.

FRONT-PAGE PATTERNS

LEARNING OBJECTIVE: *Identify the patterns used to design the front page of a ship or station newspaper.*

So far in this chapter, we have concerned ourselves with the tools and the basic principles of producing a newspaper. In this final section, we will examine the patterns followed in designing the front page of newspapers to give you, as a potential or current editor, a starting point for designing your own.

The following are three different meanings to the word *design* in the newspaper lexicon:

1. It refers to the basic format of the entire newspaper.
2. It refers to the arrangement of news on an individual page after that page has been made up.
3. It is used as a slightly altered form of the word *makeup*.

“Makeup” consists of building a page, element by element, until all the space on a page is filled, but “design,” using the third definition, means to plan for the total structure of a page before any layout is done.

Logically, it requires more time to “design” a page than to “make up” one. Consequently, when the pressure of a deadline is present, your most important concern is meeting that deadline. However, when there is ample time for preplanning, as is the case with most weekly issues of a newspaper, you should “design” the front page, if not every page.

The primary purpose of designing a page is to **make it easier to read**. This enables your readers to cover the material faster, and as a result, it encourages more of them to read all that is written. Remember, unread copy serves no useful purpose. When you design your front page, it is important for you to note that there is no “best” pattern, only different patterns. Any design repeated too often loses any freshness it may have had, and of itself, becomes a deterrent to the enjoyment of the reader. Consequently, a good editor will vary those patterns from issue to issue.

Not unlike other aspects of our culture, newspapers have changed over the years and are still changing. A number of editors, however, remain devoted to what is called “traditional” style and continue to design their publications accordingly. Others have opted to follow or to lead the way in developing modern journalistic trends by producing newspapers with a “contemporary” style. Undoubtedly additional styles will be forthcoming as tastes continue to change. Meanwhile, the traditional patterns currently in use are covered in the following text.

TRADITIONAL PATTERNS

The term *traditional patterns* (fig. 8-23, views A through D) refers to the following front-page design strategies:

- Formal balance
- Quadrant

A. Formal Balance

B. Quadrant

C. Focus (Brace)

D. Circus (Razzle-Dazzle)

Figure 8-23.—Front-page design strategies; (A) Formal balance; (B) Quadrant; (C) Focus (Brace); (D) Circus (Razzle-Dazzle).

- Focus (brace)
- Circus (razzle-dazzle)

Formal Balance

In formal balance design (fig. 8-23, view A), the page is vertically divided in half. Each element to be placed on one side of the vertical centerline is duplicated by the same treatment of elements at the same point on the opposite side. In this type of design, there are two lead stories; both are usually of equal importance.

Formal balance design forces the news into a formula and does not distinctly tell the relationships, values and relative worth of the news. It also creates an artificial look, with the makeup being the dominant factor on the page. It is considered “visually boring” by modern editors. Most editors still using formal balance vary its use often enough to escape the deadening effect of sameness (fig. 8-23, view A).

A variation of formal balance is the dynamic (informal) balance design. It follows the same fundamental principle as described in the formal balance design, except when you progress below the horizontal fold of the page. This is where the exact duplication of the formal balance design is abandoned.

Since the dynamic balance design gives the editor more latitude in designing the page, it is slightly more pleasing to the eye.

Quadrant Design

In quadrant design (fig. 8-23, view B), the page is divided into four quarters, and a dominant, eye-stopping element (picture or headline) is placed in each quarter so that diagonal quarters balance each other. The diagonal line, then, is the type of line used. In this type of design, the lead story is placed in the upper left-hand corner or the upper right-hand corner, depending on which is being used as the focal point of the page.

Quadrant design formalizes quarter-page balance and is useful for giving equal display to equally important stories (fig. 8- 23, view B).

Focus (Brace) Design

In focus (or brace) design (fig. 8-23, view C), the page is made up by placing headlines and pictures on the page to form a diagonal line from the upper

left-hand corner to the lower right-hand corner. Then a strong typographical display is used in the upper right-hand corner for sharp emphasis. The diagonal line is the type of line used here. In this type of design, the lead story is placed in the upper right-hand corner.

A letter or figure pattern is discernible in the focus design. Note in figure 8-23, view C, that the figure “7” is apparent in the pattern. Also note that attention is “focused” on the corners by the stair-step arrangement of headlines that appear to “brace up” those corners (fig. 8- 23, view C).

Focus design is useful when you have one story that outweighs any other in news value. It also is useful in getting readers to read through the page.

Circus (Razzle-Dazzle) Design

In circus (or razzle-dazzle) design (fig. 8-23, view D), the page is made up by placing elements on the page so all elements scream for the reader’s immediate attention. Therefore, there is no focus of interest on the page.

The circle is the type of line used in the circus design. In this type of design, the lead story is placed in the upper left-hand corner or the upper right-hand corner, depending on which you are using as the focal point of the page.

Circus design is characterized by immense type, large art masses arrayed in unorthodox shapes and positions, use of colored ink for headlines, use of white space, movement of the nameplate to a minor spot on the page, use of widely varying headline typefaces with emphasis on the boldest weights and preference for multicolumn displays.

Because it is difficult (if not impossible) to make up a page so no one item stands out above any other, circus design is probably the most difficult design to use successfully (fig. 8- 23, view D).

CONTEMPORARY PATTERNS

While not really offering a new concept in newspaper style, the following design concepts represent a break from the pure traditional patterns:

- Functional
- Horizontal
- Modular
- Total/Single Theme
- Grid

Functional Design

In functional design, the page is made up according to no set pattern. It is based on presenting the day's news in the way that will be most appealing and convenient to the reader. The vertical line, diagonal line, circular or horizontal line could be the type of line used in functional design. In this type of makeup, the lead story is placed in the upper right-hand corner (fig. 8-24).

Functional design always lets the news dictate the layout and is characterized by very few banner headlines. It often has stories that run over the nameplate and uses short and floating nameplates, kickers, down-style headlines and several pictures. Functional design uses no decks on headlines and avoids jumps. (Headlines and headline terminology will be covered in detail in chapter 9.)

Horizontal Design

In horizontal design (fig. 8-25), the page is made up by placing elements on the page so the majority of the elements present a horizontal display. In this type of makeup, the lead story is placed in the upper left-hand corner or the upper right-hand corner, depending on which one you use as the focal point of the page.

Horizontal design provides strong horizontal units with a few vertical displays for contrast. It is characterized by large multicolumn headlines, large

Figure 8-25.—Horizontal design.

horizontal pictures, white space, and odd-column measures. This format came about as a result of readability studies, which indicate that readers estimate their reading time of horizontal copy blocks to be about half that of vertical blocks.

Horizontal modules of headlines, copy, photographs and even the flag give the page a strong horizontal thrust.

Modular Design

In modular design (fig. 8-26), pleasing blocks (modules) of vertical and horizontal rectangles are combined. Irregular story shapes are avoided to maintain this modular look. An earmark of a classic modular format is a strong vertical chimney (a panel running at least half the depth of the page) on the left or right side of the page. This chimney may contain news briefs, a complete story or only a photograph and outline. Highly flexible and uncluttered, this design gives the editor a wide range of formats for visual impact.

Total/Single Theme Design

In total/single theme design, strong emphasis is placed on a single, important story or issue. Both emphasize simplicity with strong visual impact.

The total page design may contain a large photograph (or line art) covering the entire area, a

Figure 8-24.—Functional design.

Figure 8-26.—Modular design.

single story and photograph, or a billboard (dominant photograph with page reefers to major stories).

The single theme page design is essentially similar, but normally does not contain stories or reefers. If you use this design strategy, make sure you stick with the theme and develop it on subsequent pages. You might have a single-page feature, two or three major stories about various aspects of the theme throughout the newspaper, a photo feature or any combination of these elements.

Figure 8-27 shows an example of a total page design.

Grid Design

The grid design (fig. 8-28) consists of a page of modules of varying sizes with the grid lines formed by the spaces between columns and the spaces separating stories.

A grid design is a pattern of intersecting lines, forming rectangles of various shapes and sizes. The objective of this concept is to take advantage of contemporary artistic principles to give a page the “now look” found in today’s magazines. Lacking the flexibility of other patterns, the grid design cannot be combined with other makeups but must stand alone as a single unit. Its intersecting lines are highly structured

Figure 8-27.—Total page design.

Figure 8-28.—Grid design.

and carefully placed to divide a newspaper page into clean-cut, simple-appearing modules whose total effect is contemporary. Stories are squared off and designed into vertical or horizontal shapes with the division of space on the page always arranged in unequal portions. The page might be divided (from left to right) into two and four columns or one and five columns, but never three and three.

The top of the page is never top heavy as is the case in traditional designs. While story placement is still based on the importance of giving a particular story featured treatment, the grid design allows all other

stories a better chance of being seen, since they are not buried or lost to the reader (fig 8-29).

FINAL NOTE

Remember that the front-page designs covered in this chapter are only suggestions for what you can do with your newspaper. A pure sample of a formal page layout is nearly impossible to find, because experienced editors are not concerned with producing textbook examples. Rather, their interest is in presenting the news of a particular day in what they believe is the best and most interesting manner. Most often that is done by combining features of several page patterns.

As you gain experience as a layout editor and become familiar with established patterns, you can try out new ideas as they come to you. Trust your instincts and do not be afraid to experiment. A controversial page design is better than a dull, uninviting one.

Figure 8-30.—Grid design examples.

CHAPTER 9

WRITING HEADLINES AND CUTLINES

You have just delivered a story to your associate editor that is the best you have ever written. The lead is first-rate, the body copy is flawless and the ending is textbook.

However, the story might vanish into obscurity on any newspaper page if the accompanying headline does not entice or inform the reader.

Well-written headlines grab the reader's attention, convey clear, concise thoughts and dress up the publication. Poorly written headlines can mislead, confuse, and even embarrass the newspaper staff, command and Navy. Headlines must be free of libelous statements and must not contain violations of security, accuracy, policy and propriety.

A reader often decides whether to read a story based on what the headline says. A headline tempts the reader to dig into the story. To do this, you, as a headline writer, must have a sense of what will attract the reader. You must have a broad vocabulary and enough versatility to say the same thing several ways to make sure the headline will fit the space allotted for it on the page.

In the following text, we cover the essentials you need to become an effective headline writer. Additionally, we examine the methods used to write cutlines (the explanatory matter supplementing photographs) in the final third of this chapter.

HEADLINE EVOLUTION

LEARNING OBJECTIVE: *Evaluate the evolution of the headline.*

The first American newspaper headlines were nothing more than labels. A large capital letter, called an "initial letter," may have been used to set off the first paragraph of each story. Sometimes the front-page headlines were one-line labels showing the origin of the news (England, France, Spain).

By the time of the Revolutionary War, American newspapers had made some progress in the art of writing headlines, but not much. A full-page account of the battle between the *Bon Homme Richard* and HMS *Serapis*, for example, might have been carried

under a 10-point, Old English typeface headline that read as follows:

Epic Sea Battle

An epic sea battle between the Bon Homme Richard and the HMS Serapis was waged on the high seas. ...

During the Civil War, American newspapers began putting more information in their headlines, but their form was very different from what we are accustomed to today. Figure 9-1 shows a multidecked headline carried by the *New York Sun* over the story of the assassination of President Lincoln in 1865.

Toward the turn of the century (during the Spanish-American War), technical improvements and a circulation war between the Hearst and Pulitzer newspapers in New York helped speed the adoption of multicolumn headlines. Important stories were introduced by screaming headlines (banners) across the entire page, followed by as many as eight or more related heads. Sometimes headlines occupied more space than their stories.

However, by the end of World War I, many editors began experimenting with headlines that were more streamlined and more compact. They found the space they saved could be used more advantageously for news and advertising—especially advertising, which then, as now, paid the bills.

HEADLINE FUNCTIONS

LEARNING OBJECTIVE: *Recognize the functions of the headline.*

The modern trend in headlines is toward simplicity. Most newspapers now use heads that say what has to be said in a minimum of words. A good headline conveys the news in a story and the significance and meaning behind the story. It never implies more—and should not say too much less—than what actually appears in the story. It does not contain misleading suggestions and it does not leave false impressions.

An easy way to remember the functions of the headline is through the acronym **HEADS**:

Figure 9-1.—Multidecked headline from the New York Sun following the assassination of President Lincoln.

H - Heralds the days news; tells what is of importance.

E - Entices the reader with essential or interesting facts.

A - Advertises the most important story by size or placement on the page (the most important stories are displayed at the top of the page).

D - Dresses up a page with typography; helps make design attractive.

S - Summarizes the story with a “super” lead; tells what the story is about.

HEADLINE STYLES

LEARNING OBJECTIVE: *Recognize the various types of headline styles.*

There are several ways in which you can display headlines. For style variation, your headlines can be

set in all-caps, caps and lowercase or downstyle. These methods are covered in the following text.

ALL-CAPS HEADS

The all-capital letter headline style is almost extinct. All-caps heads, while they are easier to write than others, are the most difficult to read. To test this premise, read the following paragraph:

AS THIS PARAGRAPH DEMONSTRATES, THE ALL-CAPITAL SETTING IS NEITHER EFFICIENT FOR THE READER, NOR PLEASING TO THE EYE. WILLIAM RANDOLPH HEARST USED TO HAVE KEY GRAPHS IN HIS EDITORIALS SET ALL-CAPS. INSTEAD OF MAKING THE POINT EMPHATICALLY, AS HE INTENDED, SUCH SETTING ACTUALLY CUT DOWN THE READERSHIP AND ITS IMPACT.

Even the most patient, attentive and skilled reader will be blinded by the onslaught of all those capital letters. By the way, did you spot the typo? Emphatically is misspelled.

CAPS AND LOWERCASE HEADS

A widely used headline style is the uppercase and lowercase head. In this headline style, all words, other than articles, conjunctions, and prepositions of fewer than four (and sometimes five) letters, are set with the first letter in caps and the others in lowercase.

DOWN-STYLE HEADS

The down-style head usage has increased in popularity in recent years. In down-style heads, the first letter of the first word—and the first letter of any proper noun—is set as a cap, and all other letters are lowercase. Down-style is presented in the way persons are taught to read and write. The style is visually attractive and enhances the readability of the line. By design, it lacks the numerous capital letters in a headline which serve as “eye stoppers.”

HEADLINE FORMS

LEARNING OBJECTIVE: *Identify the most common headline forms.*

Headline forms constantly come and go. Regardless of the form, the most common headlines

are easy to read, easy to write, and easy to set. Some of the most common headline forms are explained in the following text.

BANNER HEAD

The banner head (fig. 9-2) is set the full-page width at the top of a news page to draw attention to the lead story or that particular page. If you run a banner head above the flag or nameplate, it is called a **skyline**. A **streamer** applies to the widest and biggest multicolumn head on a page, regardless of whether it is the full width.

CROSSLINE HEAD

The crossline head (fig. 9-3) is very similar to a banner headline. Although it does not always span the full width of the page, it does cover all the columns of the story to which it pertains.

FLUSH LEFT HEAD

The flush left head (fig. 9-4) is a two- or three-line head with each line set flush left. The lines do not have to be equal in width or set full. The white space at the right is considered enhancing, because it allows "air" into the otherwise stuffy column spaces. Flush left is the most commonly used head today.

NEX gift certificates great holiday gift idea

Do you have a hard time selecting the right gift for everyone on your holiday list? Do you spend hours guessing at the proper size and color? If this is you, your holiday shopping just got a lot easier.

Navy Exchanges have just introduced a new worldwide NEX gift certificate. The new gift certificates are available and redeemable at any Navy Exchange around the world. They come in three convenient denominations — \$10, \$25 and \$50. Select the amount that's right for you.

Navy Exchange gift certificates aren't just for Christmas either. They make the perfect gift for birthdays, weddings or any other special occasion.

Since gift certificates are good at any Navy Exchange, at home or abroad, they are the gift that's easy to send to friends and family wherever they may be located. However, the person receiving the certificates must be an authorized Navy Exchange customer in order to enjoy using the gift certificates.

Navy Exchange gift certificates are easy to buy, too. Just see the customer service representative at your local NEX.

Pick up Navy Exchange gift certificates for everyone on your list this season. They are the gift that always fits. Your Navy Exchange makes holiday giving and holiday shopping a pleasure.

Figure 9-4.—Flush left head.

SIDE HEAD

The side head (fig. 9-5) is a headline form that runs alongside a story. It is normally three or four lines and looks best when set flush right. A side head is usually placed slightly above the center of the story.

KICKER

The kicker (fig. 9-6) opens up the area on a page where the headline is located. It can be used to

Local pilot had unique role in Desert Storm

Story and photo by
Vance Vasquez

Two years ago, Jan. 17, the United States and other United Nations coalition forces joined together to liberate occupied Kuwait from Iraqi forces.

Operation Desert Storm affected the lives and careers of thousands of military personnel by participating in the first Congressionally-authorized war since World War

II. One such person, Cmdr. Robert E. Noziglia Jr., aircraft maintenance officer of Naval Air Weapons Station, Point Mugu, had a unique role in Desert Storm.

Noziglia was interviewed by Ambassador Edward W. Genhum, Jr., the U.S. designate for Kuwait, in Washington D.C., Sept. 15, 1990. He was selected to head the reconstruction of the Kuwait Air Force.

A Kuwaiti 747 airliner

was used to transport 86 contract technicians along with their supplies to Khams Mushayt, Saudi Arabia. They departed from Andrews Air Force Base, Md., and arrived in Saudi Arabia, Sept. 16, 1990.

"The technicians were both retired Navy and Marine Corps personnel with A-4 Skyhawk experience," said Noziglia.

When Iraq invaded Kuwait and overwhelmed the

small country, only a small portion of the Kuwait Air Force was able to escape into Saudi Arabia. A total of 18 A-4KU and two TA-4KU skyhawk, attack aircraft along with 15 F-1 Mirage fighters and three L110-30 (C-130) transport aircraft were saved.

The Kuwait Air Force arrived with no support facilities available; no equipment, tools or aircraft log books, which were left be-

hind in Kuwait.

"The aircraft was unique since no other country operated A-4KU Skyhawks; we were able to assemble new log books from information obtained from the United States," said Noziglia.

After the technicians arrived 34 days later, the A-4KU's were moved from Khams Mushayt and were forward-deployed to Dhahran, Saudi Arabia. The A-

4KU's were stationed far away from Iraq to avoid any possible airstrikes before the United Nations mandate for Iraq to leave Kuwait was ordered. The Kuwait Air Force was integrated with The Royal Saudi Air Force (RSAF) under a single command.

The coalition forces of France, Qatar and Kuwait operated the F-1 Mirage.

Expanded dependents dental plan nears implementation

(ARNEWS) — More details were set for the expanded Dependents Dental Plan, in a workshop held by the Office of the Civilian Health and Medical Program for the Uniformed Services (CHAMPUS).

Enrollment in the expanded benefits plan will be automatic

for all sponsors with eligible family members, even if the sponsor had previously declined enrollment or had disenrolled from the basic plan.

However, sponsors stationed outside the continental United States when the extended plan begins will not be automatically enrolled, unless they are

already enrolled in the basic plan.

There will be a 90-day disenrollment period for those who wish to decline the new

program. Some issues still remain open, such as the monthly premium, co-payment cost and a premium rate for junior soldiers.

Figure 9-3.—Crossline head.

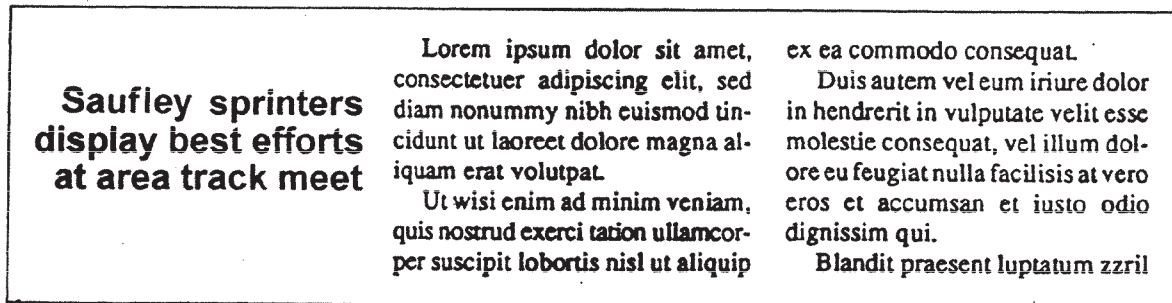

Figure 9-5.—Side head.

Figure 9-6.—Kicker.

introduce a feature article with a pun line above the main head.

The following are some basic rules for you to follow when writing kickers:

- Extract kicker information from the bridge or the body of the story.
- Do not repeat words in the kicker and main head. Interpretation of the main head should not depend on information in the kicker.
- Make the kicker 1/2 the point size of the main head. For example, a 36-point main head will have an 18-point kicker.
- Set the kicker 1/3 to 1/2 the width of the main head. For example, a three-column main head requires a one-column to 1 1/2-column kicker.
- Alternate type postures to give the head the proper emphasis. For instance, a roman style main head requires an italic kicker and vice versa.

- Indent the main head two counts (headline unit counting will be explained later) under the kicker to add white space.
- Always underline the kicker.
- Do not use a kicker at the top of a page.

HEADLINE VARIANTS

LEARNING OBJECTIVE: *Recognize the most common variations of standard headlines.*

There are countless variations of headline styles, all of which are viewed in terms of their visual impact when used with basic headline styles. Some of these variants are explained in the following text.

STANDING HEAD

The standing head (fig. 9-7) is essentially a label used for regular or recurring content, such as sports and chaplains' columns. It does not change from issue to issue.

Figure 9-7.—Standing head.

Figure 9-8.—Jump head.

JUMP HEAD

The jump head (fig. 9-8) is designed to help the reader find a portion of a story continued from another page. The jump head uses one or two key words from the headline that introduced the story. It is set flush left followed by the words “Continued from Page ##,” usually set in boldface body type (it also can be set in italic). A two-point rule may be used to extend from the side of the head over the width of the article.

HAMMER HEAD

Often called a **reverse kicker**, the hammer head (fig. 9-9) is set twice the size of the main head, set flush left, and is no wider than half the width of the headline area.

TRIPOD HEAD

The tripod head (fig. 9-10) is a single, short line of larger type set to the left of two lines of smaller type. The tripod portion (larger wording) should be twice the

size of the definition or main headline. For example, a 36-point tripod would dictate that the main head be set in 18-point type to give the true tripod appearance. Punctuation in the form of a colon is required when the tripod conveys a separate thought.

WICKET HEAD

The wicket head (fig. 9-11) is a tripod in reverse (short line of larger type set to the right of two lines of smaller type). The colon is not used in the wicket. Although it is seldom used, on occasion, you may consider it to vary your newspaper design.

NOVELTY HEAD

The novelty head (fig. 9-12) features typographical tricks, such as setting part of the head upside down, using an ornate typeface or substituting artwork as characters. Use the novelty headline sparingly with appropriate feature articles. Overuse of this headline may lead to your readership questioning the credibility of the newspaper.

HEADLINE WRITING SKILLS

LEARNING OBJECTIVE: *Recognize the components and attributes required in headline writing.*

Headline writing requires skill and concentration. Your headline must give the essence of the story. While explaining the story accurately, your headline also must fit into a limited space.

Some copy editors approach headline writing by looking for a key word or two that expresses the high point of the story. Then they add other words until they have a headline. Other copy editors begin by forming a sentence that contains the essential elements of the story. Then they edit out excess words (adverbs, adjectives, articles and so forth) and minor details until all that is left is a well-tailored headline that tells the story essentials.

Headlines are written in *telegraphic English*, a term coined because they closely resemble the wording found in most telegrams. While the consideration in telegrams is mostly monetary, the economical consideration of headlines is space. Therefore, headlines usually contain—as the “bare bones” of language—a subject and verb. Other strong uses of telegraphic English might include subject-predicate or subject-verb-object constructions.

A straight news headline is written for a straight news story and a feature headline for a feature story. If the story is a colorful account of some event or trip, the headline should be colorful. If the story is a romantic or dramatic account of an event, the headline should

follow form. If it is a human-interest story with an element of pathos, the headline should not be humorous. If the story is humorous, the headline should not evoke pity or compassion.

In the following text, we will cover some of the general principles of headline construction practiced by most copy editors.

USE OF VERBS

The key to good headline writing is the use, whenever possible, of strong action verbs. Headline writers use verbs in what is sometimes called the “historical present” tense—meaning they use the present tense verb to describe action that has already happened. Primarily, this tense is used to convey a sense of immediacy, in the same way many people normally speak in the present tense to describe exciting experiences to friends. Present tense verbs contain fewer letters than do their past tense forms.

Verbs may be omitted when implied. For example, the verb “appears” is implied in the following headline:

Acadia Boatswain's Mate On 'Supermarket Sweep'

However, do not overuse this approach. Action verbs are still best for capturing a reader's attention. The verbs **is** and **are** are frequently understood. It is not necessary to use them except for clarity. The infinitive “to be” is also awkward in headlines and you should avoid using it. Note the following examples:

Poor: New pay raise is approved

- Better:** New pay raise approved
- Poor:** Halloween Dance to be held
Oct. 31 at Fleet Park
- Better:** Halloween Dance slated
Oct. 31 at Fleet Park

Do not begin a headline with a verb that might convey the imperative mood (implying a command). Note the examples that follow:

- Poor:** Reject new pay hike
for armed forces
- Good:** Armed forces pay hike
rejected by Congress
- Better:** Congress rejects
new pay hike for armed forces

To give the reader a better sense of immediacy, the verb should be in the first line of a headline whenever possible. When you can avoid it, do not place the verb in the bottom line of a three-line head.

ARTICLES

Omit all articles (a, an, the) and other unnecessary words. Note the following example:

- Poor:** Today's submariners are "lucky" says
veteran of the USS *Grant*
- Better:** Today's submariners "lucky" says USS
Grant veteran

VOICE

Use the active voice in preference to the passive voice whenever possible. Note the following examples:

- Poor:** More pilots being sought for T-45 test
- Better:** Navy seeks more pilots for T-45 test
- Poor:** Navy flight training bolstered by
new T-45
- Better:** New T-45s bolster Navy flight training

DECKS

Make each deck (not necessarily each line) a complete construction. Write the headline so it will stand alone and make sense, especially when you use it as the main deck. Consider the following example:

- Poor:** Decade of off-duty study earns degree
at Memphis

- Better:** Memphis chief earns law degree
after decade of off-duty study

Because headlines are restricted to a small space, copy editors generally limit headlines to one specific idea expressed forcefully, rather than several ideas expressed vaguely. If space permits, editors sometimes connect two independent thoughts by a semicolon in a headline—or add another section to the headline (a second deck)—to include additional important aspects of the story.

If a story involves a plane crash that kills one crew member, injures the pilot, and disrupts a training exercise, you should limit the main deck to the death. Subordinate headlines, or the story, should cover the other news.

BE SPECIFIC

As with all forms of news writing, the use of specifics is better than generalities. Note the following headline:

Auto crash
proves fatal

This headline does not contain nearly as much information as the headline that follows:

2 die as car
smacks tree

BE POSITIVE

Another custom most headline writers observe is phrasing headlines in a positive, rather than in a negative manner. This is based on the principle that a newspaper is supposed to tell readers what **did** happen, not what **did not** happen.

When writing about a family that escapes injury when their car overturns and burns on a highway, a novice headline writer would probably write the following:

No one hurt
in car fire

Given the same story, a good headline writer composes the following headline:

Family escapes
flaming death

OPINIONS

Headlines on stories dealing with opinion should show the source of that opinion. If a story is attributed

to a secondhand source, this should be reflected in the headline. Consider the following examples:

‘Courts too lenient’
claims parish priest

NFL players unhappy
with owners’ offer
says arbitrator

REPEATS

You should avoid repeating words in the same headline deck. Also, watch out for similar phraseology in adjacent heads and decks. Consider the following example:

Former *Abraham Lincoln* journalist
returns to *Abraham Lincoln*
as public affairs officer

THE FIVE Ws

A good headline generally has the **who** and the **what** of the story in the first line, with the following lines explaining the **how** and **why**, if necessary.

People expect newspaper stories to concern events that have occurred since the previous edition was published. Therefore, the **when** can usually be omitted. If an event is yet to happen, however, warn the reader by the inclusion of the **when** through the use of the future tense or a specific day or date.

The **where** in a headline on a local story is generally omitted. Readers expect their newspapers to print local stories and will assume a story is local unless the dateline or headline specifies otherwise.

SHORT SYNONYMS

Use short, vigorous words. Headline writers usually have a vocabulary all their own. They learn to think in terms of short synonyms for longer expressions when writing headlines. Many copy-editing texts contain lists of short synonyms for headline use. Note the following examples:

- **Named** for appointed or elected
- **Set** for arrange or schedule
- **Win** for victory
- **Ex** for former

- **Job** for appointment or position
- **OK** for accept, approve or adopt
- **Try** for attempt
- **Vet** for veteran
- **Hike** for raise or increase
- **Tell** for reveal or inform

In addition to these synonyms, many more are commonly used in Navy newspapers. Some of these are as follows:

- **Sub** for submarine
- **Flyer** or **pilot** for aviator
- **Jet** for jet-propelled aircraft
- **All hands** for entire ship’s company
- **Ships** for reenlists
- **Crew** for crew members
- **Plane** for aircraft or airplane
- **XO** for executive officer
- **CO** or **skipper** for commanding officer or captain

SPLITS

Do not split words, phrases, proper nouns or compound nouns between lines. Note the following examples:

Words:

5,000 PO1 advance-
ments predicted off
September examinations

Phrases:

Crew members of
USS *Basil Fome*
visit Funafuti

Proper Names:

Capt. Robert J.
Macron assumes
command of HC-16

Compound Nouns:

Saufley chief petty
officers sponsor
orphans’ picnic

LINE BALANCE

Try to balance headlines typographically.
Consider the following examples:

Unbalanced:

Navy, Coast Guard icebreakers
save U.K. ship

Balanced:

Navy, Coast Guard icebreakers
rescue grounded U.K. corvette

ABBREVIATIONS

You should use commonly known and accepted abbreviations when they are appropriate. Do not be afraid to use Navy abbreviations for ships, aircraft, ratings, ranks, commands, titles and so forth, in ship and station publications.

The following are some commonly used Navy abbreviations:

- **CPO** for chief petty officer
- **PO1, PO2** and **PO3** for petty officer grades
- **ComRats** for commuted rations
- **NCO** for noncommissioned officer
- **LDO** for limited duty officer
- **GQ** for general quarters
- **SecNav** for Secretary of the Navy
- **CNO** for Chief of Naval Operations

Use these and other Navy abbreviations **only** in ship or station publications. Never use them in press releases to civilian news media. For further information, consult the latest edition of *The Associated Press Stylebook and Libel Manual*.

PUNCTUATION

Newspaper editors generally adhere to the following style for headlines:

- Use single quotation marks instead of double.
- Use commas to replace the word *and*. Also, where natural, use commas to make pauses or breaks in headline construction.
- Use semicolons to divide thoughts, where needed, especially three-line heads.
- Use periods only after abbreviations.

- In a caps and lowercase head, start each line and every important word with capital letters.
- Articles (which are rarely used) and prepositions (which do not lead off a line) are **not** capitalized in a caps and lowercase head.

CUTLINES

LEARNING OBJECTIVE: Recall the methods used in gathering material for cutlines and identify cutline components, typography, layout, and datelines.

Photographs have a unique storytelling ability. They are most effective when accompanied by some explanatory text.

A missile launching may make an exciting photograph, but it fails as a news vehicle unless the reader understands the **when, where** and **why** of the photograph, as well as the more obvious **what** and **how**.

The function of providing information the photograph does not furnish is performed by the photograph's cutline, also known as a photo caption. A cutline supplements the photograph by explaining action, naming people and giving background information.

The cutline writer is normally a middleman, who takes a photograph (which is inflexible) and adds the cutline (which is flexible) and comes out with a story. The cutline writer determines what additional information must be given to communicate the story the photograph is meant to tell.

Cutline writing is a specialized form of newswriting. It answers the same basic questions as the news story. Yet, it does this in a single, concise paragraph. The cutline writer must be alert to answer any questions the photograph may arouse in the reader's mind.

GATHERING CUTLINE INFORMATION

There is no secret formula to gathering cutline information. However, there are certain practices you should follow that will allow you to write effective cutlines after you return to your office. These practices are covered in the following text.

How to Record Cutline Information

Cutline information may be recorded in a notebook or a locally designed "caption log." A

caption log may serve as a handy reminder of what information you should record. An example of a locally designed caption log is shown in figure 9-13.

What Outline Material Is Recorded

When you gather material for outlines, you generally use the same methods and techniques as for gathering information for a news story. The major difference is that you do not need as much information, but it must be pertinent to the scene in the photograph.

The following are a few points to consider before you write a outline:

- What is the storytelling value of the photograph?
- Is the photograph intended for internal or external use? (Photographs for civilians may need more information.)
- Will the photograph be released to a hometown paper? If so, you must include a hometown tie-in.
- Will the photograph be used alone or with a story?

With these basic considerations in mind, try to stick with the old but reliable five Ws (and H) when you gather outline material. Find the answers to the most pertinent questions, and you will have more than enough information to write your outline.

WHO.—Identify people in the photograph by rank, full name, title, hometown and so forth. Also note relative positions of people in the photograph when there are more than one and if it is not obvious who is who by action, age, gender or rank. Sometimes it is helpful for you to note the clothing or physical characteristics of the people being photographed. Keep in mind that when you or your photographer use black-and-white film, it will do little good to note “yellow T-shirt” or “red dress” on the caption log. However, such notations as “Mets T-shirt,” “sunglasses,” or “curly blond hair” will prove helpful.

WHAT.—The “what” can apply to two areas. First, it may involve what is happening in the photograph. In the caption log, it may be necessary to jot down a word or two to describe the action. For example, “slicing cake,” “performing PMS check,” or “donning EEBD.”

PHOTOGRAPHERS NAME		DATE AND TIME
SUBJECT/SLUG		LOCATION
POC NAME AND PHONE		ROLL #
FRAME #	ACTION	I.D. (NAMES, EQUIPMENT, LANDMARKS)

Figure 9-13.—Sample caption log.

Second, the “what” may entail equipment in the photograph. Unusual equipment often is included in photographs. The equipment should be identified. An OBA may not require identification, but an OBA with a lifeline attached may need further elaboration. Ships and aircraft should always be identified. Never guess or suppose you know the proper nomenclature; ask an expert on the scene.

WHERE.—Make sure you record the location of the action. Write down the name or number of street names, building names or numbers and so forth. If there are landmarks, either natural or man-made, identify them as well. These might include rivers, lakes, statues, bridges and mountains.

WHEN.—Record the time and date the photograph was taken. This is especially important for “wild” or “stand-alone” photographs that will not be accompanied by a story.

WHY.—Unless it is obvious, record why an action is taking place. Is it part of a base basketball championship or a monthly awards ceremony? As in the “when” category, this is important for photographs that will stand by themselves.

HOW.—If there are circumstances that led to the photograph being taken and they require explanation, make sure you know how they came about.

Matching Outline Information with the Photograph

You should record outline information by individual frame number. However, if you shoot several frames of the same subject and action, it is not necessary for you to record information each time. Simply list the range of frame numbers in which the subject appeared.

When to Record Outline Information

Record the outline information immediately after each shot or series of shots. Do not let subjects get away without jotting down the required outline information. They may be hard or impossible to track down later, and you may forget who you shot or who was doing what in the photograph.

One exception to this practice is a sporting event where it is impossible to interrupt the action. In this instance, let the subject(s) know in advance that you will be taking photographs and will need to get identification as soon as possible after the event. Note

uniform numbers, clothing or physical characteristics. You also may record the information during breaks in the action.

CUTLINE COMPONENTS

We will not go into detail here on how your photographs should be posed and what to look for in the way of composition. This will be covered in chapter 12, *Basic Photojournalism*. The primary concern now is the text that accompanies the photograph and how it should be written. Although newswriting and outline writing are closely related, they are different.

The lead in a news story is the most important part of the story. The facts presented in the lead may be expanded and elaborated on in the bridge and body of the story.

The outline differs in that it is more than a part of the story—it is the **whole** story. Everything you have to say about the photograph is said in one paragraph. That paragraph must contain the essential facts, and the facts must be tied into the scene in the photograph. The length of a outline is always governed by what must be told about the photograph. It may consist of one word, one sentence, or it may consist of five sentences.

Cutlines have no set lengths. Strive for simplicity and brevity. The shorter you can write a cutline and still include all the essential information, the better it will be.

As in headline writing, a cutline is written in a manner appropriate to the subject matter. In other words, write a news cutline for a news photograph and a feature cutline for a feature type of photograph.

There are probably as many ways to write cutlines as there are newspapers, magazines and other periodicals. Just about every publication has its own individual requirements and style of outline writing. Some want long cutlines. Some want only one or two words to tease a reader into reading the accompanying story. Others use no outline at all.

Only one method of outline writing will be covered in this chapter. It is considered the handiest formula for a novice writer and consists of the following four major components:

- The action
- The identification (persons or things in the photograph)

- The background information
- The credit line

The Action

The first sentence of a cutline is the most important. It must link with the photograph by describing its action.

One of the peculiarities of the first sentence is its verb form. The verb in the first sentence of a cutline is in the present tense. The reason for this is that photographs, like paintings and sculpture, capture one moment of time and keep it in the present.

Another reason for using the present tense in the first sentence is that it gives the readers a sense of immediacy, as though they were actually witnessing the event shown. Thus a cutline that reads, “Navy Seaman Jack Frost **swims** through swirling flood waters of the Baylinguay River to rescue 6-year-old Tia Maria...” has more dramatic impact than one that reads, “Navy Seaman Jack Frost **swam** through. ...”

One problem that arises from the use of the present tense in the first sentence is what to do with the **when** element. To put the time element in the first sentence would result in a sentence such as “Ryan Thompson hits a line drive to center field yesterday. ...” This is somewhat jarring to the reader and should be avoided.

To alleviate this problem, you can usually reserve the time element in cutlines for the second sentence. This avoids awkward sentences such as the one just quoted.

The Identification

The second part of a cutline is the identification. This includes an identification of all persons and things vital to the storytelling function of the photograph. Everyone who is involved in the central action of the photograph should be identified. Do not identify persons who are blurred out, obscured or too far away for recognition. Anyone in a photograph who attracts the reader’s attention should be identified. The reader’s curiosity should never be impeded. If the identity of a pertinent figure in a photograph is unknown, make this fact a part of the cutline.

The next question concerning identification, is where should it be placed in the cutline? The best answer is, it should come as high as possible in the paragraph. Many times it will be possible to identify people at the same time the action is described. For

example, in the statement “Seaman Apprentice Jay B. McMannus sounds taps to climax Memorial Day ceremonies....,” the identification is included as the subject of the action. Sometimes, however, it may be preferable to use an impersonal identification (such as “A Navy musician sounds ...”) in the first sentence. In that case, the complete identification should come in the second sentence.

The only exception to the ground rule previously stated is in the case of group identification. When there are several people to be identified in a photograph, it is better that you not clutter the first two sentences with a list of names. This is apt to discourage the reader from finishing the cutline. The recommended way to handle a group photograph is that you use an impersonal identification in the first sentence (such as, “A group of sailors ...”), then list the names later in the cutline. This achieves complete identification without cluttering the important first sentence.

The identification itself can be handled in one of several ways. The idea is to handle it in the most natural and concise manner consistent with clarity. The best way to identify people is by action. If Kip Karuthers is throwing a pass to Ronnie Gato, it should be obvious from the photograph which one is passing and which one is receiving the ball. Thus they are identified by their activity, and you will not have to use left and right identifications.

Another simple manner of identifying people in a photograph is by obvious contrast. If there are two Sailors and an officer in a photograph, it is not necessary to identify the officer as being to the left, or in the center. The officer is well-identified by obvious contrast, therefore, place identification would be superfluous.

Identification by elimination is slightly more complex. Suppose there are four people in a photograph. One of them is receiving a medal from another. These two are identified by the action. A third person is the award recipient’s wife. She is identified by obvious contrast. Therefore, the fourth person is identified by elimination.

For example, the identification in the cutline might be handled in the following manner:

“Lt. Wayne E. Pilot receives the Distinguished Flying Cross from his squadron leader, Cmdr. William A. Aviator. Lt. Pilot’s wife, Gertrude, and Lt. Cmdr. Thomas V. Hoek, VAP-99 XO, look on.”

Finally, there is the traditional left, right, center or “from the left” identification. It is not necessary to say “from left to right.” This wastes space. If one starts from the left, there is no place to go but right! Use this type of identification only when the other means of identification will not suffice or when there is a chance of the reader becoming confused.

In cutline identification, avoid bromides, such as “pictured above” or “shown above.” It is apparent to both the editor and the reader that something is pictured or shown above the cutline. Even worse are such phrases as “posing for this picture are ...” or “smiling for the camera is ...”

The Background Information

The third component of the cutline is the background information. This consists of additional facts or explanations needed to clarify the subject matter of the photograph. The length of this section of the cutline depends on two factors mentioned earlier: (1) where the photograph will be used and (2) how the photograph will be used.

The amount of background information needed to explain a photograph of carrier operations to a civilian reader will obviously be greater than that needed to explain it to crew members who are participating in such operations.

If a photograph is to accompany a news story, do not duplicate details used in the story. If the photograph is to be used alone, the cutline must be complete.

Cutlines prepared for picture stories are similar to those written for single photographs, except that a story is told by means of a series of related photographs. In this case, a main cutline, usually written for the lead or key photograph of the story, can supply background information for the entire story.

Although present tense is used to describe the action, the correct past, present or future tense is used when presenting background facts related to the action. However, you should be careful of changing tenses in the middle of a sentence.

The Credit Line

The last component of the cutline is the credit line. Most ship and station newspapers use credit lines for photographs.

There are several ways of crediting photographs. Some newspapers and magazines give photographers personal credit lines (this is encouraged for ship and

station newspapers). Others use a blanket statement which states, for instance, that “all photos are U.S. Navy photos unless otherwise credited.” However, the recommended way is to put the credit line at the end of the cutline itself. The credit line should follow the last word of the cutline, in parentheses, in the following manner: (U.S. Navy Photo by JO3 Evelyn Grudge) or (U.S. Navy Photo).

CUTLINE TYPOGRAPHY

If you are writing cutlines for external release, do not concern yourself with the way the cutline will be set in type. However, if you edit a ship or station newspaper, you will need some knowledge of cutline typography.

Good cutline typography heightens the impact of a photograph by making the explanatory text as visually appealing as possible. It is a good idea to rewrite and reset Navy Editor Service (NES) cutlines, because they may violate your local style, and the typefaces used may not match yours.

For better display, cutlines are usually set in a larger or a different typeface than that used in the news columns. Some papers use the same size and style as their body type, except that it is set boldface.

Cutlines under multicolumn photographs are best displayed when set two columns wide for two-column photographs (fig. 9-14) or a column-and-a-half wrapped for three-column photographs (fig. 9-15). The term *wrapped* means to place two or more columns of type side by side under one heading or piece of art. Cutlines should not be set wider than two columns.

Figure 9-14.—Cutline for a two-column wide.

Figure 9-15.—Cutline for a three-column photograph set a column and a half wide.

Captions

The word *caption*, while often used as a synonym for the word *cutline*, has a second meaning. It is a small headline, or display line, sometimes used with cutlines. Its function is essentially the same as those used over a news story as follows:

- To summarize
- To attract attention
- To dress up the page

There are several kinds of captions in this context. An **overline** runs above the photograph. An **underline** runs between the photograph and the cutline. The **side catchline** is used with photographs of three columns or more and runs on the left side of the cutline. If a headline is not used, the first few words of the cutline may be set in boldface or all capital letters to serve as a **lead-in line**. These four types of captions are shown in figure 9-16. All such display lines should be in large type, preferably the kind used in a small headline.

Mortised Photographs

Photographs that contain dead areas of sky or unimportant background can be mortised (a rectangular window, or space, is cut out and the cutline is placed in the space). This saves page space and may actually improve the photograph.

Figure 9-16.—The four basic caption forms: (A) overline, (B) underline, (C) side catchline and (D) lead-in line.

CUTLINE LAYOUT

When laying out a page, you should treat each photograph and its cutline as one unit. The relationship of photograph to cutline must be obvious. Readers will seldom spend much time hunting for misplaced cutlines. In addition, cutlines may be run beside or above photographs. This adds variety, and in some cases, enhances page layout.

It is a common practice for most newspapers to run the story and accompanying photographs side by side. Because of space limitations, however, this is impractical at times. If a story and an accompanying photograph must be separated in a newspaper for any reason, the two are still “keyed” together. For example, if the photograph

appears on page one and the story on page four, the cutline will carry a line that says “Story on page 4.” This keys the two together for the reader’s convenience.

There are times when a newspaper may not have space to publish both story and photograph. When this happens, one or the other will be discarded. If it is the story that gets the toss, the cutline must be rewritten to include more details.

When a photograph and cutline are released with a story or when you are writing a story and cutline for your command’s newspaper, the best practice is to write the story first. After the story is written, write the cutline for the photograph. There are two important reasons for this —(1) it enables you to avoid any duplication of phrases or ideas that appear in the story and (2) it enables you to write tighter, more compact cutlines. After writing the story, you have the salient features clear in your mind, and the act of paring the cutline down to its essentials becomes much easier.

DATELINES

When preparing cutlines for photographs to be released externally, you need not concern yourself with display lines. You merely write your cutline in complete and simple sentence form. An additional component must accompany a cutline for outside release —the dateline.

The dateline answers the question “where?” and is used as a lead-in to the cutline. For example, a datelined cutline might read: “ABOARD THE USS UNITED STATES AT SEA —Carrier pilots leave ...”

Additional information on datelines may be found in *The Associated Press Stylebook and Libel Manual*.

HEADLINE/CUTLINE DESIGNATORS

A headline or cutline designator is a set of numbers and letters that tell the writer of the headline (and the person who typesets it) the size and style that will be used for that headline in the layout. (See figure 9-17.)

The number before the first hyphen is the number of standard columns the headline will stretch across in your newspaper.

This tells you, the writer, how wide the headline will be, or the *column width* of the headline. Civilian enterprise publications around the country and command newspapers vary in the number of columns they use in their publications, depending on the size

Sample Headline and Cutline Designator

3-30ABI-2

Figure 9-17.—A headline or cutline designator.

and format of the paper, as mentioned earlier in this chapter.

The combination of numbers and letters between the two hyphens serves two purposes:

- The number tells the height, or *point size*, to be used when the headline is set in the newspaper. (See figure 9-17.)
- The letters in the designator indicate the type style or *font*, to be used for the actual characters. Most newspapers use *sans serif* fonts as their primary fonts. *Sans serif* are letter types, such as Arial and Helvetica, that are not decorated by “feet” and “curlicues,” as some type of fonts, like Bookman and Times New Roman.

Arial would be designated by the letter “A.” If the font is to be set in boldface, a “B” will be added to the designator. If the font is to be set in Italics, an “I” will be added.

The number that follows the second hyphen in the designator indicates how many lines the headline will occupy.

COUNTING HEADLINES

The headline designator is the key to determining how many characters will fit into the space your story will occupy in the publication. The first two numbers used in the designator, column width and point size, are used to determine how many characters and spaces will be fit into each line of the headline.

To make sure a headline fits in its allotted space, you can use a form of measurement called “unit count.” This system assigns each letter, number, punctuation mark and space character a specified number value. The area on your newspaper page is limited, so it is important to use this method carefully.

“Flirt-j” UNIT COUNT SYSTEM

Headline counting systems vary from newspaper to newspaper. However, in this section, we will explain the standard system in the newspaper industry - the “flirt-j” unit count system.

Although nearly every newspaper and publication uses computer software programs for layout, design and formatting of their publications, this method of counting headlines is still used today by many civilian enterprise publishers.

The “flirt-j” unit count system is determined by the following rules:

- All lowercase letters and spaces between words or characters receive one (1) count.
- EXCEPTIONS: **f, l, I, r, t** and **j** each receive one-half (0.5) count; **m** and **w** each receive one and one-half (1.5) count.
- All uppercase letters and all numeric characters each receive one and one-half (1.5) counts.
- EXCEPTIONS **M** and **W** each receive two (2) counts; **I** and the numeral **1** receive one (1) count.

- All punctuation characters each receive one-half (0.5) count.
- EXCEPTION: Each hyphen (-) receives one (1) count; each dollar sign (\$) or question mark (?) receives one and one-half (1.5) counts; each dash (-) receives two (2) counts.

In counting the units in a headline, you place one tick mark over each character or space that has a count of one; place two tick marks over each character that has a count of two; and place one tick mark beneath each character that has a count of one-half.

Count the number of units in the following headline:

Congress approves \$2 Billion year-end budget

If you came up with a headline count of **41.5** you are correct!

CHAPTER 10

LEGAL CONCERNS

Is the First Amendment of the U.S. Constitution the same to a reporter as an umpire's "call 'em as I see 'em" license? Is the new city official really a crafty, communist sympathizer?

To the grief of many a publisher and reporter, there is no absolute license to print whatever one pleases about a private citizen or about the government.

Free speech and free press, as guaranteed by the Constitution, have two sides: on one side, the right to use them; on the other, the duty not to abuse them. When the news media abuses its right to a free press, they commit an age-old offense known as libel — the defamation of a person's reputation.

Because your job is to write about the Navy, you should become acquainted with the danger of defamation. This chapter provides information on what you should guard against when releasing material to the news media or publishing it in internal publications. It also acquaints you with the right of privacy and some of the laws of copyright.

LIBEL AND SLANDER

LEARNING OBJECTIVE: *Recall libel and slander; identify how libel is committed and determine who is responsible for a libelous story.*

Libel is a difficult offense to describe (see fig. 10-1). Libel laws are state laws, and there are differences in the definitions of libel from state to state. For the purposes of this training manual, we will define libel as follows:

Libel is a published (written, printed or pictured) defamation that unjustly holds a person up to ridicule, contempt, hatred or financial injury.

All states agree that libel is a **defamation**, an act that tends to degrade or lower a person in the eyes of others. The effects can subject a person to ridicule, hatred or contempt (or all three), or they can cause a person financial injury by hurting the person's property or business or by causing loss of employment.

As you can see, defamation does not have to be sensational to be libelous. A picture with the people erroneously identified in the caption can be libelous. A newspaper headline, or a story posted on your command's Internet web site, even if the story under it is blameless, can be libelous.

Radio and television are not exempt from libel laws. A picture on television can be as libelous as one printed in a newspaper. A radio broadcast can defame an individual, although there is some dispute in the courts as to whether the offense would be libel or

Figure 10-1.—Radio broadcasts could contain both libel and slander.

Photo by PHC (AW) Brian Wimet

slander. Slander differs from libel chiefly in that it is spoken instead of printed, written or pictured. In other words, slander is defamation by oral communication. A major distinction between libel and slander is found in the word “published.” Since slander is an oral defamation, the courts tend to view it as a lesser offense than libel because the words, once uttered, are quickly gone. Libel, on the other hand, is a published wrong and is felt to endure longer and thus cause greater injury. Consequently, the law is much stricter in dealing with libel cases than with slander claims.

However, the subject becomes a bit cloudy when oral remarks (slander) are read from a written script or when they are recorded. Therefore, you should exercise equal care to avoid both oral and written defamatory statements.

True statements about a person also can be libelous. Many people think that libel results only from untruths told about another. This is not so. The truth can sometimes defame an individual as much as a lie.

A simple defamation, however, is not always libel. The following are three conditions that are necessary before a statement becomes libel:

- There must be a **true defamation**. In other words, a person’s character or property must in some way be degraded.
- There must be **clear identification** of the person. This identification, however, does not have to be by name. A writer (or an artist) can very easily leave no doubt in the public’s mind as to a person’s identity without mentioning the individual’s name. Even if only a few persons were to realize the person’s identity, libel is still possible.
- The libel must be **published**. This does not mean that it must be printed in a newspaper or posted on the Internet or your command’s web site. You will recall from the definition that libel can be written (as in a letter that is seen by a single third person) or it can be pictured (as in a photograph or cartoon). Spoken libel, or slander, is also considered by the courts to have been published. As a Navy Journalist, you will not have to concern yourself too much about the legal and technical differences between libel and slander. It is sufficient to know that any defamation may be considered unlawful, regardless of whether it is written or spoken. One of your jobs is to make sure that defamatory

statements do not reach print or the airwaves through a Navy news release.

Libel, as an offense, is almost as old as civilization. Many early societies punished those who would harm the name or reputation of another. Defamation before the invention of printing almost always took the form of slander. An early code of Egyptian law recognized slander as an offense against the sun god.

After the invention of printing, libel became very closely related to freedom of the press. Through history, governments have taken various and often harsh views of a free press. For centuries, the struggle for some measure of press freedom was an uphill battle. Much of the trouble encountered in striving for press freedom revolved around the fact that for a long time governments considered any adverse criticism or comment to be libelous. Thus rulers went as far as to imprison or put to death writers who had criticized them in print. Even today, in some countries, too much of the wrong kind of criticism can mean a newspaper will be closed.

A balance between ruthless suppression and license was struck by the U.S. Constitution, and the courts have strengthened this balance in the intervening years. Today, as one writer says, freedom of the press and speech is “the first principle of the Anglo-American legal structure.” He goes on to say these freedoms are a “specific legal principle defining the relationship, in a democracy, between the people and their elected representatives.”

Libel laws exist because the free press is a two-way street. There are obligations that accompany the rights of freedom of speech and press. The managers of a respectable news medium obey the libel laws not merely because they wish to avoid being sued but because they believe in the dignity of the individual (table 10-1).

HOW LIBEL IS COMMITTED

If news media commit libel today, it generally occurs in one or more of the following areas:

- Attacking a person’s character or personal reputation
- Accusing someone of a loathsome disease or insanity
- Accusing someone of a crime
- Attacking a person’s professional competence

Table 10-1.—Newspaper Headlines are not Exempt from Label Changes

Sources say ship’s captain was “Drunk”
Congressman placed at murder scene
Lawyer calls Johnson “murderer”

- Subjecting a person, in any way, to public contempt, hatred or ridicule

Instances of libel are more common than most people suspect, and court action does not have to result before a statement becomes libelous. There are hundreds of instances of libel everyday in the United States news media. The vast majority of them are minor or borderline cases, and most of the more serious ones go unnoticed or uncontested. There are relatively few court actions for libel.

RESPONSIBILITY FOR LIBEL

Let’s assume that you write a story and accidentally include a statement that offends somebody. The person offended sues for libel. Who is responsible? Who pays? A casual observer might think that in a suit against a large newspaper, any damages will be paid by the medium publishing the story. This is not necessarily so.

Technically, everybody who had anything to do with the statement may be sued. This includes you, the PAO who released it, the officer in command who is responsible for everything you release, the editor who accepted it, the editor who approved it and anybody else in the chain of events who read it, understood it, yet allowed the statement to reach print.

Another point worth emphasizing is that any person who reprints a libelous statement can be held as being just as guilty as the person who originally published it. For example, assume that one newspaper publishes a libelous statement. Another newspaper picks up the story, credits the first newspaper with the facts and republishes it. The second newspaper may be just as guilty as the first, if the case reaches court and libel is proved. In some states, charges may be brought against both newspapers.

Wire services are similarly liable. Occasionally, a newspaper will publish a wire service story that is libelous and the newspaper cannot or does not verify the facts in the story. Despite the circumstances, some

states hold that the newspaper is just as responsible as the wire service, while other states place the blame solely on the wire service. Nevertheless, a person can name anyone in a lawsuit who had anything to do with the preparation of the story or its distribution.

TYPES OF LIBEL

LEARNING OBJECTIVE: *Identify the different types of libel.*

There are two kinds of libel — obvious libel and libel by inference (hidden libel), referred to in law as **libel per se** and **libel per quod**, respectively. Do not let yourself become confused by the Latin terms.

LIBEL PER SE

The more obvious of the two, libel per se, means “by itself” or “on the face of it.” The reader or viewer does not have to interpret or study in order to understand the libel per se because it is obvious or evident. Libel per se is the more serious of the two types, and persons libeled in this manner do not have to prove that they suffered damage to their reputations, monetary loss or other injury. Libel per se can support a lawsuit in itself.

There are probably thousands of words, phrases and statements in the English language that are libelous in themselves. Some of them are of a political nature, others refer to race or religion and still others involve specific professions and occupations. Others (and this is no doubt the largest group) affect the honesty, integrity or morals of anyone to whom they are applied.

Here are just a few examples of words and phrases you should **not** use in reference to individuals or groups:

Professionals. Attorney: shyster, ambulance chaser, crafty, unprincipled and slick. Business person: swindler, racketeer, double-dealer, cheat, and

phony. Politician: liar, grafter, perjurer, seller of influence, pocketer of public funds and criminal's partner. Doctor: quack, abortionist, faker and incompetent. Also, **never** use such words as crooked and criminal to describe people or their behavior.

- **Affiliations.** Red, Communist, Nazi, a member of the Ku Klux Klan, atheist, nudist and socialist (sometimes).
- **Honesty and Morals.** Unreliable, a credit risk, hypocrite, adulterer, unchaste, prostitute, drunkard, conspirator, mistress and thief.

Obviously, there can be many more classifications of words and phrases that are libelous in themselves. For example, a word like “drunkard” can have numerous synonyms, all just as libelous, and the same thing applies to most of the nouns and adjectives in the preceding list.

Another point worth considering is that the meanings of words and phrases can and do change. Over a period of years the meaning of a word or phrase can shift gradually until it is no longer libelous in itself or libelous at all. The reverse also is true. A word or phrase harmless a few years ago may be libelous in itself today.

A word that has almost entirely lost a previous libelous per se meaning is “alcoholic.” A few years ago the word was synonymous with “drunkard,” but today it refers to an illness — alcoholism. Words of this type, however, should still be used with caution.

As for a word's evolution from the inoffensive to potentially inflammatory, do you remember when “gay” only meant happy and carefree?

In a libel suit, if the defamatory material is libelous in itself, the court decides on the interpretation of the words and phrases involved; the news medium does not. If the court decides the material can be understood as libelous by the public, the publisher involved has no argument.

LIBEL PER QUOD

The second type of libel is committed by inference and is more “hidden.” Its legal term, libel per quod, means “because of circumstance” or “by means of circumstance.” In libel per quod, the statements, words or phrases involved may be harmless in themselves, but become libelous because of attached circumstances. Usually, such circumstances are unforeseen by the publisher, who can claim that the questionable material

was published in good faith and without malice. However, good faith is not a complete defense.

Here is a classic example of libel by circumstance: A news story reported an athlete's spectacular feats on the tennis court the previous Saturday. In fact, the tennis match was on Friday, not Saturday; a simple error. However, the story was libelous per quod because the athlete in question belonged to a religion that observes Saturday as the Sabbath — a day of quiet and meditation. The story, as it was printed, defamed the athlete as not being a devout member of his church.

Libel per quod is the most common of all libels. Very few publishers intentionally undertake the risk involved in printing material that is obviously libelous. However, libel per quod often occurs because of errors or negligence. There are countless other examples of libel by circumstances — wrong names, wrong addresses and so forth.

Libel by circumstances also may result from what the reader may infer. In a story appearing in a national magazine, a man was described as being a legislative representative (lobbyist) for the Communist Party. The man charged in a suit that this statement damaged his reputation because it implied he was a communist sympathizer. Whether the man was, or was not, a communist sympathizer or a lobbyist for the party was beside the point. The man claimed he had been defamed, and his claim was upheld by a federal appeals court.

“Guilt by association” also is a form of libel per quod. This form of libel, sad to say, has been employed for many years by unscrupulous politicians and others seeking positions of power.

Perhaps the most obvious use of this method has been the linking of various persons to the Communist Party by innuendo. During a political campaign in the west several years ago, pamphlets appeared describing a U.S. senator who was running for re-election, as being friendly toward communist aims. One of the principal items of evidence given to support this claim was the fact that the senator had participated in a pre-World War II meeting during which Russia and Stalin were praised as foes of Nazi Germany. The pamphlets were clearly an example of circumstantial libel — what the reader might infer. The intent of the writers of the pamphlet was apparently to damage the senator's reputation in order to injure his election prospects.

LIBEL AND THE LAW

LEARNING OBJECTIVE: *Recognize the laws that apply to civil and criminal libel and the defenses against libel action.*

We have pointed out that the laws of libel are state laws, unlike the U.S. Constitution or other national laws that bind **all** U.S. citizens. Libel laws vary from state to state with each state free to make changes in its libel code whenever it chooses. As a result, there is little uniformity among the states regarding award of damages or the nature of judgments in similar types of libel cases.

The state laws of libel are complex and can be understood thoroughly only by an attorney or a person trained in this field. In this section of the chapter, we only describe some of the “ground rules” that generally apply in all states.

There are two types of legal action that can result from publication of libelous material: **civil action** and **criminal action**.

CIVIL LIBEL ACTION

Civil libel action results when one person sues another in court because of alleged defamation. This defamation, again, need not be to the individual’s character or reputation. It can be to a person’s business, occupation or property.

Civil libel also can be committed against a legal “person” composed of more than one individual. In this regard, a corporation, a partnership or any other association of individuals can be defamed. General Motors could sue an individual for defaming its products or business practices. Also, an individual could sue General Motors. One corporation also can sue another corporation.

Individuals cannot sue the U.S. government, however, unless it consents to the suit. When people feel they have been libeled by an agency of the government, they still cannot bring suit unless the government agrees to be sued.

Civil libel suits are always between persons, whether the “person” is an individual, an association of individuals or an artificial being, such as a corporation. A sum of money is the usual compensation awarded by civil courts for damages. The amount has varied from one cent, a nominal sum to indicate vindication, to millions of dollars.

Money awarded in libel cases is intended to compensate the injured party for mental or physical suffering and for actual financial loss and to punish the individual or individuals who committed the libel.

CRIMINAL LIBEL ACTION

Criminal libel action is less common than civil libel action, but it is much more serious. Criminal libel is a crime and can be prosecuted in the courts like any other crime. In criminal libel the state is the accuser and the punisher. Persons convicted of criminal libel can be fined, imprisoned or both, depending on the gravity of the offense.

Any libel that tends to disturb public peace and order can be a criminal offense. For instance, if a popular public figure were to be libeled to the extent that riots resulted, the libel would be of a criminal nature. Obscene libel can be a criminal offense because it is considered to have an ill effect on public morals.

One of the most grave types of criminal libel is seditious libel — that which defames an established government, or one of its agents, in an attempt to thwart or overthrow it. Criminal libel, if directed at the U.S. government, becomes a federal offense and can result in a long prison term for the libeler. Seditious libel is rare, but it has occurred in cases when news organizations or individuals have written violent defamations of the government in their opposition to federal laws or the decrees of federal courts. Mere opposition to a court decree is not necessarily libelous (though it could be seditious). Remember, there is no libel involved until there is defamation.

DEFENSES AGAINST LIBEL ACTION

An individual, a newspaper or other news organization is not without some degree of protection when being sued for libel. In the following text, we cover some of the partial and complete defense strategies that might lessen the damages assessed against a defendant in a libel suit.

Partial Defenses

There are eight basic partial defenses against libel action, as covered in the following text.

INNOCENT MISTAKE/ACCIDENT.—The first mitigating factor to consider is innocent mistake, or accident, which appears in the libel codes of most states. Almost self-explanatory, it means that a

defendant can be excused partially if it can be proved the libelous material was published unintentionally or without the publisher realizing it was defamatory. The “innocent mistake” law does not remove liability, but it may reduce it.

RETRACTION, APOLOGY OR CORRECTION.—A retraction, apology or correction, usually printed with the same prominence as the original libelous material, will sometimes satisfy a person who claims to have been libeled. Nevertheless, the libeled party still retains the right to bring suit. Although retractions, apologies and corrections are three separate (partial) defenses, they are related and often overlap. A retraction is often accompanied by a correction when it is employed, and both, almost always, are accompanied by an apology. One disadvantage of a retraction, or apology, is that it puts the original defamatory remark before the public eye again, although hopefully, in a much nicer form.

An example to the contrary is this story about a southern editor of a few years ago: The editor was bitterly opposed by certain people in the town and did not hesitate to become quite harsh on them in print. One man insisted he had been libeled and demanded a retraction. The next issue of the paper appeared with the following line in large type:

JOHN GREEN IS NOT A BRAYING ASS

In that example the editor successfully and wittily continued his feud; but regrettably, he also compounded the original libel.

REPETITION.—The defense of repetition can be used when a newspaper uses a libelous story that has been printed elsewhere, in a wire service article for example. In a number of recent court decisions, newspapers were not held responsible for libels committed by wire services, since it was recognized that editors could not possibly check out every story received from those sources.

LACK OF MALICE.—In the lack of malice defense, punitive damages are usually not awarded if the publisher can demonstrate good faith and justifiable ends.

SELF-DEFENSE/REPLY.—A self-defense or reply defense can sometimes be successful if the publisher can show that the libel was a response to a previous attack made by the person claiming libel.

UNCONTRADICTED RUMOR.—The uncontradicted rumor defense can sometimes serve to

lessen the damages that could be awarded in a libel case if the publisher can show that the libel was merely a published version of widely circulated rumors that the plaintiff had made no effort to deny.

USE OF AUTHORITY.—In employing the use of the authority defense, a publisher would try to show that the libel originated from a source that could reasonably be expected to be accurate. A successful presentation of this defense, while not exonerating the publisher, could serve to lessen the damages awarded.

PRIOR BAD REPUTATION.—A prior bad reputation defense might prove useful to a publisher accused of libel if it could be shown that the plaintiff already had an unsavory standing in the community and the defamatory statement caused very little additional injury.

Keep in mind that these partial defenses are just that — partial. They may lessen punitive damages, or in some cases eliminate them, but they do not excuse the libel charge.

Complete Defenses

The seven complete defenses against libel charges can absolve the publisher of all liabilities if successfully used. Incidentally, it is important for you to note that in libel cases, unlike other cases tried in our country’s judicial system, the burden of proof is on the accused, not on the plaintiff or the prosecution.

TRUTH.—Truth is the best complete defense against libel action. Some state laws read that truth alone will suffice as a defense in a civil libel suit; others maintain that the truth must be “without malice.” In either case, the facts published must be provably true.

If the law requires “truth without malice,” the defendant also must prove good intentions. Malice, however, as judged by the courts today, does not mean only “intent to harm.” The consensus appears to be that “truth without malice” must be “truth for a good reason.” The good reason is usually judged by determining if the material presented is in the best interest or concern of the public.

For example, a newspaper prints a story about a man running for a high public office and states that the candidate has served a prison term for embezzlement. The statement is true, and the newspaper’s reason for printing it is the belief in the public’s right to know, or the “public good.” The candidate’s history, in this instance, would give reasonable doubt of his qualifications for public office.

If, however, the same statement had been made about a private citizen who was in no way connected with the public welfare, there would have been no “good reason” for publishing that information.

FAIR COMMENT AND CRITICISM.—A publisher can claim the fair comment and criticism defense in many instances. The courts are often lenient when fair comment or criticism is made of a political organization or any powerful corporation; in reviews of television programs, movies, plays and books; or in articles dealing with officials or agencies of the U.S. government. It has been established that one of the chief functions of the news media is to serve as a critic of the wielders of public or private power. The courts reason that this function should not be arbitrarily suppressed.

Many newspapers engage in “crusades” against a dishonest or bungling government and against crooked gambling or other criminal activities. As long as a newspaper approaches such a “crusade” in a responsible manner, it is well within its rights. Every year Pulitzer Prizes are given to individual reporters for either having exposed private or public abuses of power, and in some cases, having caused their corrections.

PRIVILEGE.—Privilege, as a defense against libel, deals with legislative and judicial operations. There are two kinds of privilege. One is “absolute privilege;” the other is “qualified privilege.”

Absolute Privilege.—Absolute privilege protects those directly involved in judicial proceedings (judges, attorneys and witnesses) and legislative matters (the President, governors, mayors and lawmakers at the federal, state, county and city levels). Absolute privilege does not apply to the news media.

Qualified Privilege.—Qualified privilege does apply to the news media and affords them qualified, or conditional, protection in reporting public and official proceedings. The conditions for this protection are that a story must be characterized as follows:

1. Fair, accurate and complete
2. Without malice
3. Published for justifiable ends

The one limitation of qualified privilege is that a story must not include any obscenity. Other than that, legislative and judicial proceedings may be reported in their entirety, regardless of the truth or falseness of what is said. The legal theory supporting this license

holds that the public interest in public matters should be served, even at the expense of individual defamation.

Remember, however, that this privilege does not cover the reporting of conventions of private organizations, such as political parties, labor unions and churches.

LACK OF PUBLICATION.—Lack of publication as a complete defense is more likely to be used in a libel case involving some form of personal communication that may or may not have been seen by a single third party. This defense could hardly serve the needs of a newspaper publisher whose product is seen by large numbers of people.

LACK OF DEFAMATION.—The lack of defamation defense is used when a publisher believes that no one has been defamed; and therefore, if it can be proved, there is no basis for a libel suit.

CONSENT.—Consent, as a libel defense, is used by a publisher when it can be shown that the person claiming libel previously consented to the statement that is now being challenged.

STATUTE OF LIMITATIONS.—Statute of limitations, as a complete defense against libel, means that a libel action was not brought within a maximum period of time as specified by law. The time limit varies from one year from the date of publication, in some states, to as many as three years in others. Beyond whatever deadline is established, no suit may be filed.

THE PRIVACY ACT

LEARNING OBJECTIVE: *Identify the basic provisions of the Privacy Act.*

All Navy Journalists must have a working knowledge of the Privacy Act (PA) of 1974. The PA is an enclosure to the *Department of the Navy Privacy Act (PA) Program*, SECNAVINST 5211.5.

PRIMARY FEATURES

Under the PA, government agencies may collect, store, disclose, account for and amend required personal information on military and civilian government employees. Additionally, individuals may request access to information about themselves. In the Navy, personal information may be collected and stored in roughly 200 PA record systems. An example

of such a system is the Navy Civilian Personnel Data System (NCPDS).

The premise of the PA is simple. Everyone has a constitutional right to privacy. People do not waive that right simply because they are in the military or work for the government. Therefore, when you write a story about a person, there are a limited number of facts that may be released without the permission of that person.

RELEASABLE INFORMATION—MILITARY

In the case of a military person, the following facts may be released:

- Name
- Rank
- Date of rank
- Gross salary
- Present and past duty assignments (subject to limitations addressed in SECNAVINST 5211.5)
- Future assignments that are officially established (subject to limitations addressed in SECNAVINST 5211.5)
- Office or duty telephone numbers
- Source of commission
- Promotion sequence number
- Awards and decorations
- Attendance at professional and military schools (major area of study, school, year of education and degree)
- Duty status at any given time

RELEASABLE INFORMATION—CIVILIAN

When releasing information about government civilian employees, you may include the following facts without approval from the individuals concerned:

- Name
- Grade or position
- Date of grade
- Gross salary
- Present and past assignments
- Future assignments, if officially established

- Office telephone number

The point for you to remember is that, without a compelling reason that is usually in connection with the public concern, a person's privacy should not be violated. For you to pry into an individual's home life in connection with a news story is inexcusable unless there is some clear public need for the information. On the other hand a person cannot claim the right of privacy if an important news event has placed an individual, willingly or unwillingly, in public view. Even so, this does not give the news media the right to push human dignity and decency aside.

Additional information on the PA may be found in SECNAVINST 5211.5 or in *PA Regs*, chapter 7.

THE FREEDOM OF INFORMATION ACT

LEARNING OBJECTIVE: *Identify the basic provisions of the Freedom of Information Act.*

The Freedom of Information Act (FOIA) was established in 1966 to give the public the right to access records of the executive branch of the federal government. It established for the first time in U.S. history the right of "any person" to seek access to these records.

More than 40,000 FOIA requests are received annually from organizations and individuals. Requests center on the programs and activities of the DoD, including (but not limited to) the following:

- Projected retirees
- Decklogs
- Investigations
- Contracts
- Nuclear weapons
- Disposal of toxic substances

AGENCY RECORDS

The FOIA provides for access to U.S. government "agency records" — simply stated, products that result from the gathering of data. They may include records originated by the agency or those it has received and maintained at the time of the FOIA request. Some examples of agency records include the following:

- Books
- Papers

- Maps
- Photographs
- Machine-readable materials or other documentary materials regardless of physical form or characteristics (see figure 10-2).

You also must be aware of the records that **do not** qualify for release under the FOIA. Some of these records include the following:

- Objects or articles (such as structures, furniture, paintings, sculpture, three-dimensional models, vehicles and equipment)
- Administrative tools (such as computer software)
- Nontangible records (such as an individual's memory or oral communication)
- Personal records not subject to agency creation/retention (such as notes to jog the memory of an employee)
- Unaltered publications and processed documents available to the public through other means (such as regulations, maps and manuals)

FOIA REQUEST FORMAT

A request for an agency record under the FOIA must follow a specific format. First, and most important, make sure the request is in writing. Do not process verbal requests, whether in person or on the telephone. Additionally, the request must indicate that it is made under the provisions of the *Department of the Navy Freedom of Information Act (FOIA) Program*, SECNAVINST 5720.42, or its parent directives, DoD 5400.7 or DoD 5400.7-R.

The request also must contain a reasonable description of the record(s) requested. This will enable you or others in your office to research the request with more efficiency.

FOIA FEES

All fees related to an FOIA request must be paid by the organization or person making the request. For commercial requesters, fees are assessed for the search, review and duplication of the requested records. All fees \$15 or under are automatically waived. However, in the case of educational institutions, noncommercial scientific institutions and news media representatives, fees can only be assessed

Figure 10-2.—All photographs should be checked for security violations before being released.

(Photo by PH3 Natalie Nolen)

for duplication (after the first 100 pages). All fees \$15 and under may be waived.

FOIA ASSISTANCE

Occasionally, you will receive an FOIA request that does not meet the format previously described. Since members of the public usually do not understand FOIA request procedures, it is up to you to help them.

TIME LIMITS

You must respond to FOIA requests within 10 working days. However, this may be an unrealistic length of time because of your work schedule. When this happens, you may take a formal time extension of up to 10 additional working days if you must take one or more of the following actions:

- Search for or collect records that are located, in whole or in part, at places separate from the office processing the request.
- Search for, collect and examine a substantial number of records in response to a request.
- Consult with another naval activity or another agency which has a substantial subject matter interest in the determination of the request.

If you opt for a formal time extension, advise the requester in writing and give the reason(s) for the extension. Also indicate that the requester may make an appeal to the appropriate appellate authority (such as the judge advocate general or general counsel) within 60 calendar days.

Keep in mind that formal time extension letters must be approved and signed by higher authority. In FOIA terminology, this person is called the initial denial authority (IDA).

The purpose of this section is to acquaint you with some of the basic provisions of the FOIA Program. More detailed information can be found in SECNAVINST 5720.42 and in *PA Regs*, chapter 7.

COPYRIGHT

LEARNING OBJECTIVE: *Define copyright and recognize its provisions.*

Another area of legal concern to the Navy Journalist is the laws governing copyright, which, unlike libel laws, are federal statutes.

The copyright system is explained in detail in the Copyright Act of 1976 (Title 17 of the United States Code), which became effective on January 1, 1978. This act was the first general revision of the copyright law of the United States since 1909. It made a number of changes in our copyright system, and for the most part, supersedes the previous federal copyright statute.

DEFINITION

Copyright, according to the act, is a form of protection provided by the federal government to the authors of “original works of authorship fixed in any tangible medium of expression, now known or later developed, from which they can be perceived, reproduced or otherwise communicated, either directly or with the aid of a machine or device.”

Works of authorship include the following categories:

- Literary works
- Musical works, including any accompanying words
- Dramatic works, including any accompanying music
- Pantomimes and choreographic works
- Pictorial, graphic and sculptural works

- Motion pictures and other audiovisual works
- Sound recordings

It should be noted, however, that “copyright protection for an original work of authorship does not extend to any idea, procedure, process, system, method of operation, concept, principle or discovery, regardless of the form in which it is described, explained, illustrated or embodied in such work.”

Some other categories of material generally not eligible for statutory copyright protection include the following:

- Works that have not been fixed in a tangible form of expression; for example, choreographic works that have not been notated or recorded, or improvisational speeches or performances that have not been written or recorded
- Titles, names, short phrases and slogans; familiar symbols or designs; mere variations of typographic ornamentation, lettering or coloring; mere listings of ingredients or contents
- Works consisting entirely of information that is common property and containing no original authorship; for example, standard calendars, height and weight charts, tape measures and rules and lists or tables taken from public documents or other common sources

Where copyright protection applies, it is available to both published and unpublished works. The Copyright Act generally gives the owner the exclusive right to do and to authorize others to do the following:

- To reproduce the copyrighted work in copies or phonorecords (phonorecords, for the purpose of this section, refers to material objects embodying fixations of sounds, such as cassette tapes, CDs or LPs)
- To prepare derivative works based upon the copyrighted work
- To distribute copies or phonorecords of the copyrighted work to the public by sale or other transfer of ownership or by rental, lease or lending
- To perform the copyrighted work publicly in the case of literary, musical, dramatic and choreographic works, pantomimes, motion pictures and other audiovisual works
- To display the copyrighted work publicly in the case of literary, musical, dramatic and

choreographic works, pantomimes and pictorial, graphic or sculptural works, including the individual images of a motion picture or other audiovisual work

LIMITATIONS

It is illegal for anyone to violate any of the rights provided to the owner of copyright by the act. These rights, however, are not unlimited in scope. In some cases, these limitations are specified exemptions from copyright liability.

One major limitation is the doctrine of “fair use,” which is now given a statutory basis by section 107 of the act, which states: “... the fair use of a copyright work, including such use by reproduction in copies or phonorecords or by any other means specified (in section 106 of the act), for purposes such as criticism, comment, news reporting, teaching (including multiple copies for classroom use), scholarship or research is not an infringement of copyright. In determining whether the use made of a work in any particular case is a fair use, you should consider the following factors:

1. The purpose and character of the use, including whether such use is of a commercial nature or is for nonprofit educational purposes
2. The nature of the copyrighted work
3. The amount and substantiality of the portion used in relation to the copyrighted work as a whole
4. The effect of the use upon the potential market for or value of the copyrighted work

In other instances, the limitation takes the form of a “compulsory license” under which certain limited uses of copyrighted works are permitted upon payment of specified royalties and compliance with statutory conditions.

INFRINGEMENT

To use any of the exclusive rights of a copyright owner without permission is an infringement of copyright. Infringement is in violation of the law, and as such, it is punishable by the courts.

The owner of a copyright, upon proving that an infringement has occurred, can expect to recover from the offender any monetary loss suffered as well as any profit realized by the offender due to the infringement.

When a copyright is infringed by or for the U.S. government, the exclusive remedy of the copyright

owner is, with the government’s permission, to bring suit against the United States in the Court of Claims. Government employees, including military personnel, are not personally liable for copyright infringement occurring in the performance of their official duties. In cases involving Navy personnel, claims of copyright infringement may be settled before the time suit is brought by the Secretary of the Navy or his duly authorized representative, the Chief of Naval Research or his designee.

To avoid the possibility of infringement, the best policy is to request permission from the owner before using any copyrighted material. The basic guidance for the procedures to be followed in obtaining copyright permission is contained in *Permission to Copy Materials Subject to Copyright*, SECNAVINST 5870.5 series, which covers the use of copyrighted materials in Navy publications, motion pictures, audiotapes and videotapes and similar works.

USE OF GOVERNMENT PUBLICATIONS

Any material published by or for the U.S. government, or any reprint in whole or in part thereof, is generally considered to be in the public domain and not subject to copyright laws. However, when copyrighted material is used (with permission) in a government publication, it cannot be reproduced by a private citizen or in another government publication without again requesting permission from the copyright owner. Copyrighted material in a government publication must have a statement identifying the copyright holder and indicating that permission has been granted for its use (see figure 10-3).

Figure 10-3.—Registered trademarks, such as the AFIS and AFRTS logos, are also protected by copyright laws.

COPYRIGHT OWNERSHIP

Copyright protection exists from the time the work is created in fixed form; that is, it is an incident of the process of authorship. The copyright in the work of authorship immediately becomes the property of the author who created it. Only the author or those deriving their rights through the author can rightfully claim copyright.

In the case of works made for hire, as is the case when military personnel or civilian employees of the federal government author a “work” on government time, the employer and not the employee is presumptively considered the author. Section 101 of the copyright statute defines a “work made for hire” as the following:

1. A work prepared by an employee within the scope of his employment.
2. A work specially ordered or commissioned for use as a contribution to a collective work, as a part of a motion picture or other audiovisual work, as a translation, as a supplementary work, as a compilation, as an instructional text, as a test, as answer material for a test or as an atlas, if the parties expressly agree in a written instrument signed by them that the work shall be considered a work made for hire.

The authors of a joint work are co-owners of the copyright in the work unless there is an agreement to the contrary.

Copyright in each separate contribution to a periodical or other collective work is distinct from copyright in the collective work as a whole and vests initially with the author of the contribution.

Mere ownership of a book, manuscript, painting or any other copy or phonorecord does not give the possessor the copyright. The law provides that transfer of ownership of any material object that embodies a protected work does not of itself convey any rights in the copyright.

Minors may claim copyright, but state laws may regulate the business dealings involving copyrights owned by minors. For information on relevant state laws, you may wish to contact your local bar association.

COPYRIGHT AVAILABILITY

Copyright protection is available for all unpublished works regardless of the nationality or domicile of the author.

Published works are eligible for copyright protection in the United States if any one of the following conditions are met:

- On the date of first publication, one or more of the authors is a national or domiciliary of the United States or is a national, domiciliary or sovereign authority of a foreign nation that is a party to a copyright treaty to which the United States also is a party or is a stateless person wherever that person may be domiciled.
- The work is first published in the United States or in a foreign nation that, on the date of first publication, is a party to the Universal Copyright Convention; or the work comes within the scope of a presidential proclamation.
- The work is first published on or after March 1, 1989, in a foreign nation that on the date of first publication, is a party to the Berne Convention; or, if the work is **not** first published in a country party to the Berne Convention, it is published (on or after March 1, 1989) within 30 days of first publication in a country that is party to the Berne Convention.
- The work is first published on or after March 1, 1989, and is a pictorial, graphic or sculptural work that is incorporated in a permanent structure located in the United States; or, if the work, first published on or after March 1, 1989, is a published audiovisual work and all the authors are legal entities with headquarters in the United States.

SECURING A COPYRIGHT

The way in which copyright protection is secured under the present law is frequently misunderstood. No publication or registration or any other action in the Copyright Office is required for copyright to be secured under the new law. This differs from the old law, which required either publication with the copyright notice or registration in the Copyright Office.

Before 1978, statutory copyright was generally secured by the act of publication with notice of copyright, assuming compliance with all other relevant statutory conditions. Works in the public domain on January 1, 1978, (for example, works published without satisfying all conditions for securing statutory copyright under the Copyright Act of 1909) remain in the public domain under the current act.

Statutory copyright also could be secured before 1978 by the act of registration in the case of certain

unpublished works and works eligible for ad interim copyright. The current act automatically extends to full-term copyright for all works in which ad interim copyright was existing or could be secured on December 31, 1977.

Under the new law copyright is secured automatically when the work is created, and a work is “created” when it is fixed in a copy or phonorecord for the first time. Generally, “copies” are material objects from which a work can be read or visually perceived either directly or with scripts, sheet music, film, videotape or microfilm. As mentioned earlier, phonorecords are material objects embodying fixations of sounds. This also applies to a work, such as a song, fixed on sheet music (“copies”), CDs (“phonorecords”) or both.

If a work is prepared over a period of time, the part of the work existing in fixed form on a particular date constitutes the created work as of that date.

PUBLICATION

Publication is no longer the key to obtaining statutory copyright as it was under the Copyright Act of 1909. However, publication remains important to copyright owners.

The Copyright Act defines publication as follows:

“Publication is the distribution of copies or phonorecords of a work to the public by sale or other transfer of ownership or by rental, lease or lending. The offering to distribute copies or phonorecords to a group of persons for purposes of further distribution, public performance or public display, constitutes publication. A public performance or display of a work does not of itself constitute publication.”

Further coverage of the definition of “publication” is contained in the legislative history of the act. The legislative reports define “to the public” as distribution to persons under no explicit or implicit restrictions with respect to disclosure of the contents. The reports state that the definition makes it clear that the sale of phonorecords constitutes publication of the underlying work; for example, the musical, dramatic or literary work embodied in a phonorecord.

The reports also state that it is clear that any form or dissemination in which the material object does not change hands — for example, performances or displays on television — is not a publication no matter how many people are exposed to the work. However,

when copies or phonorecords are offered for sale or lease to a group of wholesalers, broadcasters or motion picture theaters, publication does take place if the purpose is further distribution, public performance or public display.

Publication is an important concept in the copyright law for several reasons:

- When a work is published, it may bear a notice of copyright to identify the year of publication and the name of the copyright owner and to inform the public that the work is protected by copyright. Works published before March 1, 1989, **must** bear the notice or risk loss of copyright protection.
- Works that are published in the United States are subject to mandatory deposit with the Library of Congress.
- Publication of a work can affect the limitations on the exclusive rights of the copyright owner that are set forth in sections 107 through 120 of the law.
- The year of publication may determine the duration of copyright protection for anonymous and pseudonymous works (when the author’s identity is not revealed in the records of the Copyright Office) and for works made for hire.
- Deposit requirements for registration of published works differ from those for registration of unpublished works.

NOTICE OF COPYRIGHT

LEARNING OBJECTIVE: *Recognize how a notice of copyright is displayed on a copyrighted work.*

For works first published on and after March 1, 1989, use of the copyright notice is optional, though highly recommended. Before March 1, 1989, the use of the notice was mandatory on all published works, and any work first published before that date must bear a notice or risk loss of copyright protection. (The Copyright Office does not take a position on whether works first published with notice before March 1, 1989, and reprinted and distributed on and after March 1, 1989, must bear the copyright notice.)

Use of the notice is recommended because it informs the public that the work is protected by copyright, identifies the copyright owner and shows the year of first publication. Additionally, in the event

that a work is infringed, if the work carries a proper notice, the court will not allow a defendant to claim “innocent infringement” — that is, that he did not realize the work is protected. (A successful innocent infringement claim may result in a reduction in damages that the copyright owner would otherwise receive.)

The use of the copyright notice is the responsibility of the copyright owner and does not require advance permission from, or registration with, the Copyright Office.

FORM OF NOTICE FOR VISUALLY PERCEPTIBLE COPIES

The notice for visually perceptible copies should contain the following three elements:

- **The symbol** © (the letter *C* in a circle), the word “Copyright” or the abbreviation “Copr.”
- **The year of first publication of the work.** In the case of compilations or derivative works incorporating previously published material, the year date of first publication of the compilation or derivative work is sufficient. The year date may be omitted where a pictorial, graphic or sculptural work, with accompanying textual matter, if any, is reproduced in or on greeting cards, postcards, stationery, jewelry, dolls, toys or any useful articles.
- **The name of the owner of copyright** in the work, an abbreviation by which the name can be recognized or a generally known alternative designation of the owner. Note the following example:

© 1993 Jack Crevalle

The “C in a circle” notice is required only on “visually perceptible copies.” Certain kinds of works, for example, musical, dramatic and literary works, may be fixed not in “copies” but by means of sound in an audio recording. Since audio recordings, such as audiotapes and phonograph discs, are “phonorecords” and not “copies,” there is no requirement that the phonorecord bear a “C in a circle” notice to protect the underlying musical, dramatic or literary work that is recorded.

FORM OF NOTICE FOR PHONORECORDS OF SOUND RECORDINGS

The copyright notice for phonorecords of sound recordings has somewhat different requirements. The notice appearing on phonorecords should contain the following three elements:

- **The symbol – (the letter *P* in a circle)**
- **The year of first publication** of the sound recording
- **The name of the owner of copyright** in the sound recording, or an abbreviation by which the name can be recognized, or a generally known alternative designation of the owner. When the producer of the sound recording is named on the phonorecord labels or containers and when no other name appears in conjunction with the notice, the producer’s name should be considered a part of the notice. Consider the following example:

Jack Crevalle

POSITION OF NOTICE

The notice should be affixed to copies or phonorecords of the work in such a manner and location as to “give reasonable notice of the claim of copyright.” The notice on phonorecords may appear on the surface of the phonorecord or on the phonorecord label or container, provided the manner of placement and location gives reasonable notice of the claim. The three elements of the notice should ordinarily appear together on the copies or phonorecords.

PUBLICATION INCORPORATING UNITED STATES GOVERNMENT WORKS

Works by the U.S. government are not eligible for copyright protection. For works published on and after March 1, 1989, the previous notice requirement for works consisting primarily of one or more U.S. government works has been eliminated. However, use of the copyright notice for these works is still strongly recommended. The use of a notice on such a work will defeat a claim of innocent infringement, as previously described, **provided** the notice also includes a statement that identifies one of the following:

- Those portions of the work in which copyright is claimed.

- Those portions that constitute U.S. government material. Note the following example:

© 1993 Jack Crevalle. Copyright claimed in chapters 7-10, exclusive of U.S. government maps.

Works published before March 1, 1989, that consist primarily of one or more works of the U.S. government **must** bear a notice and the identifying statement.

UNPUBLISHED WORKS

The copyright notice is not required on unpublished works. To avoid an inadvertent publication without notice, however, it may be advisable for the author or other owner of the copyright to affix notices to any copies or phonorecords that leave his control.

CORRECTING ERRORS AND OMISSIONS

Unlike the law that was in effect before 1978, sections 405 and 406 in the new Copyright Act provide procedures for correcting errors and omissions of the copyright notice on works published on or after January 1, 1978, and before March 1, 1989.

Generally, the omission or error does not automatically invalidate the copyright in a work if registration for the work has been made before, or is made within five years after the publication without notice. Also, to add the notice to all copies or phonorecords distributed to the public in the United States after the omission has been discovered, a reasonable effort is required.

Before 1978 (as a condition for copyright protection), the copyright law required all copies published with the authorization of the copyright owner to bear a proper notice. When a work was published under the copyright owner's authority before January 1, 1978, without a proper copyright notice, all copyright protection for that work was permanently lost in the United States. The new copyright law does not provide retroactive protection for those works.

COPYRIGHT REGISTRATION

LEARNING OBJECTIVE: *Recognize the procedures used to obtain a copyright and the rules that apply to the copyright owner.*

Generally, copyright registration is a legal formality intended to make a public record of the basic facts of a particular copyright. However, except in one specific situation, registration is not a condition of copyright protection. That exception is contained in sections 405 and 406 of the Copyright Act. The act provides that copyright registration may be required to preserve a copyright that would otherwise be invalidated because of the omission of the copyright notice from the published copies or phonorecords, omission of the name or date or a certain error in the year date.

Even though registration is not generally a requirement for protection, the copyright law provides several inducements or advantages to encourage copyright owners to register. Some of these advantages are as follows:

- Registration establishes a public record of the copyright claim.
- Before an infringement suit may be filed in court, registration is necessary for works of U.S. origin and for foreign works not originating in a Berne convention country.
- If made before or within five years of publication, registration will establish prima facie evidence in court of the validity of the copyright and of the facts stated in the certificate.
- If registration is made within three months after publication of the work or before an infringement of the work, statutory damages and attorney's fees will be available to the copyright owner in court actions. Otherwise, only an award of actual damages and profits is available to the copyright owner.

Registration may be made at any time within the life of the copyright. Unlike the law before 1978, when a work has been registered in unpublished form, another registration is not necessary when the work is published, although the copyright owner may register the published edition, if desired.

REGISTRATION PROCEDURES

If you choose to register your work, you should send the following three elements to the Copyright Office in the same envelope or package:

- A properly completed application form
- A fee of \$20 for each application

- A deposit of the work being registered

The deposit requirements will vary in particular situations. The general requirements are as follows:

- If the work is unpublished, one complete copy or phonorecord
- If the work was published in the United States on or after January 1, 1978, two complete copies or phonorecords of the best edition
- If the work was first published in the United States before January 1, 1978, two complete copies or phonorecords of the work as first published
- If the work was first published outside the United States, whenever published, one complete copy or phonorecord of the work as first published
- If the work is a contribution to a collective work and published after January 1, 1978, one complete copy or phonorecord of the best edition of the collective work

NOTE: The Copyright Office has the authority to adjust fees at five-year intervals, based on the charges in the Consumer Price Index. Contact the Copyright Office for the most current fees.

COPYRIGHT DURATION

A work that is created (fixed in tangible form for the first time) on or after January 1, 1978, is automatically protected from the moment of its creation and is ordinarily given a term enduring for the author's life — plus an additional 50 years after the author's death. In the case of "a joint work prepared by two or more authors who did not work for hire," the term lasts for 50 years after the last surviving author's death. For works made for hire and for anonymous and pseudonymous works (unless the author's identity is revealed in Copyright Office records), the duration of

copyright will be 75 years from publication or 100 years from creation, whichever is shorter.

Works that were created, but not published or registered for copyright before January 1, 1978, automatically have been brought under the statute and are now given federal copyright protection. The duration of copyright in these works generally is computed in the same way as for works created on or after January 1, 1978; the life-plus-50 or 75/100-year terms will apply to them as well. The law provides that in no case will the term of copyright for works in this category expire before December 31, 2002, and for works published on or before December 31, 2002, the term of copyright will not expire before December 31, 2027.

Under the law in effect before 1978, copyright was secured either on the date a work was published or on the date of registration if the work was registered in unpublished form. In either case, the copyright lasted for a first term of 28 years from the date it was secured. During the last (28th) year of the first term, the copyright was eligible for renewal. The current copyright law has extended the renewal term from 28 to 47 years for copyrights that were subsisting on January 1, 1978, making these works eligible for a total term of protection of 75 years.

Public Law 102-307, enacted on June 26, 1992, amended the Copyright Act of 1976 to automatically extend the term of copyrights secured between January 1, 1964, and December 31, 1977 to the further term of 47 years and increased the filing fee from \$12 to \$20. This fee increase applies to all renewal applications filed on or after June 29, 1992.

Under Public Law 102-307, renewal registration is optional. There is no need for the renewal filing to be made in order for the original 28-year copyright term to be extended to the full 75 years. However, some benefits accrue to make a renewal registration during the 28th year of the original term.

CHAPTER 11

BASIC PHOTOGRAPHY

How much does a Navy Journalist need to know about photography? Some JOs are expert photographers, while others resort to asking imaging facility personnel for photographic coverage of an event.

The fact remains that you will be tested on your knowledge of photography. At some point in your career, your supervisor will expect you to know the fundamentals of photography, to take news photographs with good composition, to crop and scale photos and use computer software programs to add photographs to your command publications.

If you can do these things already, you have a very important trait needed in the JO rating—**versatility**. However, if photography is not your strong suit, pay particular attention to the information in this chapter and the one that follows (“Basic Photojournalism,” chapter 12). Also, there is nothing like hands-on experience. Ask a senior JO for some on-the-job training or contact the nearest Navy imaging facility for instruction.

NOTE: Although with today’s technology it is possible to take digital photos and immediately view the final product and either save them to disk or transmit them electronically, you will still need to have a basic understanding of basic still camera fundamentals and shooting techniques. This chapter is intended to acquaint you with the basic concepts of photography. For more detailed information, consult the *Photography (Basic)* and *Photography (Advanced)* Nonresident Training Courses (NRTCs). Digital imaging is covered in chapter 8.

THE PHOTOGRAPHIC PROCESS

LEARNING OBJECTIVE: *Identify the basic process of photography.*

The basic equipment required for the photographic process, as shown in figure 11-1, includes the following components:

- A subject
- A light source
- A camera

- Photographic film
- A printing device
- Photographic paper

SUBJECT

The subject can be anything. If it can be seen, it can be photographed. Just as there must be light to form an image, there must be a subject from which to form the image.

FILM

Film, as defined in this chapter, is a light-sensitive emulsion of silver halides suspended in gelatin and coated on a transparent and chemically neutral base, usually cellulose or polymer plastic. The choice of film type is determined by the size and the sensitivity required by both the camera and the nature of the light to be used. During the exposure, silver halide crystals in the emulsion undergo an ionic change forming a latent image that can then be reduced to a visible and usable image through a complex chemical process.

CAMERA

The camera is essentially a light-tight box with an optical system at one end and an image support at the other. Additions to the basic camera have been made to improve focusing the image, viewing, controlling the amount and duration of light entering the box, film changing or rolling and range and exposure calculators. While these improvements are valuable, they are not absolutely essential to the photographic process. A picture can be made with a coffee can if it has a pinhole at one end and a support for film at the other.

Figure 11-1.—Still and digital/video cameras.

PRINTING DEVICES

Printing the negative, or making a positive, is done by contact or projection. The contact printer is usually a box with an internal light source and a piece of glass that allows light to pass through it and the negative to form a latent image on photographic paper held in contact with the negative.

The projection printer allows the image on the negative to be projected and the size of the print varied. This type of printer consists of a light source, a negative holder and a lens and focusing device mounted on a frame which can be raised and lowered, depending on the size of the projected image desired. The photographic paper is held in an easel.

PHOTOGRAPHIC PAPER

Photographic paper has essentially the same emulsion as film. The chemical process is the same as that for film but produces a positive image. Choice of paper types is dependent upon the type of printing, surface, size and finish desired.

THE 35MM CAMERA

LEARNING OBJECTIVE: *Identify the basic parts of a 35mm single-lens reflex camera.*

As a Navy Journalist, the standard type of camera you will use will be either a 35mm single-lens reflex (SLR) camera (fig. 11-2) or point-and-shoot rangefinder camera to serve as your tool to tell a story with photographs. Some public affairs offices or newspaper staffs will be equipped with digital cameras

Figure 11-2.—The 35mm single-lens reflex (SLR) camera.

and support software. For this reason it is important for you to become as familiar as possible with your camera, know what the camera can do, then know what you want it to do.

The SLR camera gets its name from the use of a mirror to reflect an image formed by a single viewing and taking lens onto a viewing screen for focusing. A cutaway view of a 35mm SLR camera is shown in figure 11-3, and the basic principle of the SLR camera is shown in figure 11-4.

Figure 11-3.—A cutaway view of a 35mm SLR camera.

Figure 11-4.—The basic principle of a 35mm SLR camera.

The mirror, set at a 45-degree angle to the optical axis, reflects the image through a pentaprism that accomplishes vertical and lateral correction of the image. At the moment of exposure, viewing is disrupted for a split second, as the spring-operated mirror swings out of the lens-to-film optical path. The mirror then automatically returns to its original position for the next exposure.

Important advantages of the SLR design are the ease of viewing and focusing and the photographer's ability to judge the effect of the depth of field at a selected aperture. Depth of field will be covered later in this chapter.

Probably the most important advantage of the SLR camera is the ease with which it can be used. Its small size and compactness enables photographers to carry them strapped around their neck or over their shoulder. Little preparation is necessary for them to be put into operation. Another advantage is the rapid film-changing devices incorporated into the cameras. They can be used to great advantage when many photographs must be made in a short period of time. Design of the average SLR camera is such that minimum time is required for making the settings and winding the film.

Because most SLR cameras make as many as 36 exposures on a single roll of 35mm film, the photographer can carry enough film in one pocket to make many exposures. This type of camera is helpful for news and action photography where several pictures must be made in a short time. It is also indispensable for color slide work.

Modern SLR cameras accept a vast assortment of lenses, ranging from fisheye to extreme long-focus types. With their interchangeability of lenses, film backs and other accessories (such as electronic flash attachments), SLRs can more aptly be called camera "systems."

Lenses are usually attached to the camera by a bayonet flange. Focusing is done by turning the lens-focusing ring. A screw thread, which runs around the inside of the lens barrel, moves the lens closer or farther away from the film, as the focusing ring is turned.

Most SLR camera lenses have an iris diaphragm. This diaphragm is held at full aperture for focusing and viewing and is stopped down automatically to the preset working aperture at the instant of exposure. This means that while the image on the viewing screen

is bright and easy to see, only the correct amount of light reaches the film for exposure.

Your SLR camera will have a built-in exposure meter that usually reads "through the lens" (TTL). The meter may measure the light falling on the mirror, the focusing screen or in some models, even on the film at the instant of exposure. On an automatic camera, the meter even adjusts the aperture or shutter speed to give the correct exposure. On manual cameras the meter produces a display in the viewfinder to indicate the correct exposure. The user then sets the camera controls to get the correct exposure.

Almost all SLRs have focal-plane shutters. They simplify the construction of the camera and make the use of interchangeable lenses easier. The shutter, aperture and mirror all work together in a precise sequence, repeated each time a picture is taken.

The relatively small size, ease and speed of operation, reliability and the high quality of photographs of the SLR cameras have combined to make it a favorite of professional photographers and photojournalists.

CONTROLS AND INDICATORS

In the Navy, most photojournalists are issued a camera kit that consists of a Canon F-1 35mm SLR camera, a 50mm lens, a 35mm lens, a 135mm lens and a flash unit. This camera is shown in figure 11-2.

Some of the main controls and indicators of the 35mm SLR camera are covered in the following text.

Film Advance Lever

The film advance lever advances the film one frame at a time, cocks the shutter, prepares the aperture and mirror for exposure and advances the frame counter one number.

Shutter Release Button

The shutter release button opens the shutter and initiates the exposure.

Shutter Speed Dial

The shutter speed dial indicates optional shutter speeds and sets the length of time the shutter remains open during an exposure. Shutter speeds are indicated

in fractions of a second; for example, $60 = 1/60$ of a second (also expressed as $1/60''$). The higher the number on the dial, the faster the shutter speed and the shorter the exposure.

ISO Indicator

The ISO (International Standards Organization) indicator allows you to compensate for the particular “speed” of your film. For example, if you are shooting black-and-white film with an ISO of 400, you will set your ISO indicator to 400. The higher the ISO, the more light sensitive the film.

Aperture Control

The aperture control is a ring around the lens with a scale listing aperture numbers (2.8, 3.5, 4, 5.6, etc.). These numbers are also known as “f/stops.” The ring sets the f/stop on the lens to control the amount of light entering the lens.

Film Rewind Knob

The film rewind knob is used to rewind the film into the cassette (film canister), to tighten slack in loaded film and to open the back of the camera. You turn the knob in the direction of the arrow to rewind the film, and lift it to open the back of the camera.

LENSES AND APERTURES

As noted previously, most 35mm SLRs have interchangeable lenses. The “focal length” of a lens is the distance from the optical center of the lens to the focal plane (film plane) when the camera is focused upon an object at infinity. A 50mm focal-length lens is considered the “normal” lens because when you look through the viewfinder, objects appear at their approximate normal size. A smaller than normal focal length (such as 28mm) means a wider angle of view. A longer than normal focal length (such as 135mm) is a telephoto lens. Focal length affects film image size.

The f/stop (aperture) ring controls the amount of light passing through the iris diaphragm of the lens and striking the film. The higher the f/stop number, the smaller the amount of light allowed to enter the camera lens. This principle works in the same manner as the iris of the human eye (fig. 11-5).

Figure 11-5.—Comparison of the iris diaphragm of a camera lens to the iris of the human eye.

OPERATING THE 35MM SLR CAMERA

LEARNING OBJECTIVE: *Determine the proper operating procedures for the 35mm SLR camera.*

In the fleet, most of the cameras you will be using today have automatic settings and are considered “point-and-shoot.” What this means is, the photographer only has to load the film correctly, turn the camera on, and capture the shot desired. This method works fine for every day photos that you may use to tell your story, but there are times when you will need to use an SLR camera that allows you to change the settings, f-stops and shutter speeds to get the shots you need. Capturing the action at a sporting event, for instance, would require you to shoot at a faster shutter speed than shooting a scene on a beach or a sunset at sea. While you do not need to know everything about SLR cameras to take good photos, you do need to know the basic principles of operation to fully understand the process. The components of a 35mm SLR camera are of little consequence if you do not know how to use them together. In this section, you will learn how to perform the following functions:

- Loading
- Holding the camera
- Focusing the camera
- Setting the film speed
- Activating the light meter

- Setting the shutter speed
- Setting the aperture control
- Shooting the picture
- Unloading the film

LOADING

You should load the camera in subdued light (not direct sunlight) and use the following method:

1. Place the film in the chamber, grasp the beginning of the film (called the leader) and feed it onto the sprockets of the take-up spool.
2. Move the film advance lever forward, depress the shutter release button and again advance the film one frame.
3. Close the back of the camera carefully and depress the shutter release button.
4. Advance the film another frame and **watch the rewind knob to make sure it moves.**

If the rewind knob does not move, either you loaded the film incorrectly or there is still some slack in the film cassette. The latter situation can be checked by gently rotating the rewinding knob clockwise without depressing the rewind button on the bottom of the camera (as is usually done when rewinding film).

HOLDING THE CAMERA

Although you may hold the camera in any manner that best suits you, give serious consideration to the method described in the following text. It will give you a steady platform for the camera that will help you reduce camera movement.

Grasp the camera on the right side with your right hand (fig. 11-6). Use the index finger of your right hand to depress the shutter release button and the thumb of your right hand to advance the film. Adjust the shutter speed control with the index finger and thumb of the right hand.

Use the index finger and thumb of your left hand to adjust the aperture and focus. For horizontal shots, place both of your elbows against your body for support. When you take vertical format shots, your left

Figure 11-6.—Holding the camera.

elbow should be placed against the body for support. Cradle telephoto lenses in your left hand.

FOCUSING THE CAMERA

A camera is focused by moving the lens closer or farther from the film (focal) plane. The two basic methods of focusing are scale focusing and SLR focusing. Both types of focusing are covered in the following text.

Scale Focusing

In scale focusing, you use a scale of distances to which the lens is set. This scale may be inscribed on the lens barrel or on the camera frame (fig. 11-7), depending on the camera design.

Scale focusing is used primarily with small aperture lenses that have sufficient depth of field to overcome small camera-to-subject distance estimate or measurement errors. To use the focusing scale, you must estimate in most cases, the camera-to-subject distance. This estimated distance is then set to the focus index mark on the lens or other focus index on the camera. The most accurate way to use focusing scales, of course, is to measure the camera-to-subject distance with a tape measure.

Figure 11-7.—Focusing scale on a camera lens.

Figure 11-8.—Split image focusing in an SLR camera.

SLR Focusing

The SLR camera has a focusing and viewing system that shows you the image formed by the taking lens. It is designed so the distance between the focusing screen and lens is exactly the same as that between the lens and the film. Therefore, whatever appears in focus on the focusing screen also will be recorded in focus on the film.

Sometimes two small prisms or a split screen is included in the central area of an SLR camera-viewing screen. When the image is out of focus, it appears split in this area. Some screens have a central grid of minute prisms that produce a shimmering effect when the image is out of focus (fig. 11-8).

You focus an SLR camera by rotating the focusing ring on the lens until the image seen on the viewing screen is in sharp focus.

SETTING THE FILM SPEED

No matter how experienced you are, you should make sure the film speed indicator matches the ISO of the film you are using. The indicator is part of the shutter speed dial of most 35mm SLRs.

ACTIVATING THE LIGHT METER

The light meter on-off switch is located on the back of the Canon F-1 (refer to the instruction manual for other camera models). A light-sensitive photocell moves a meter needle inside the viewfinder. When the meter needle is in line with the aperture needle, the camera is set for a proper exposure. The light meter can be left on throughout your shooting assignment. An example of a light meter is shown in figure 11-9.

SETTING THE SHUTTER SPEED

The film manufacturer's instructions provide time-tested shutter speeds for varying light conditions, such as sunny, overcast and cloudy. However, on occasion, you may prefer to freeze action or blur motion. In these situations you must manipulate both the shutter speed and the aperture control ring. For instance, you may set your camera at $1/60''$ to illustrate the speed of a runner—his legs and arms are a blur of motion on the finished photograph.

Consequently, if you want to freeze the action, you set your camera at $1/250''$ or higher. Then the runner's legs, arms and victory expression are "frozen." For hand-held shots, choose a shutter speed no slower than the speed closest to the focal length of the lens. For example, you would select $1/60''$ for a 50mm lens and $1/250''$ for a 250mm lens.

Figure 11-9.—Light meter.

SETTING THE APERTURE CONTROL

Adjust the f/stop on the aperture control ring to match the light meter requirement. The aperture control can be used to increase or decrease the depth of field, which will be explained in detail later in this chapter.

SHOOTING THE PICTURE

Much like pulling the trigger on a rifle, you should depress the shutter release button lightly until the camera clicks. Advance the film to the next frame and you are set for the next exposure.

UNLOADING THE FILM

One of the most common mistakes photographers make is failing to wind the 35mm film back into the cartridge **before opening the back of the camera**.

After you have exposed all frames, depress the rewind button (normally at the bottom of the camera) and slowly rewind the film. Rewinding too quickly, especially in cold weather, could crack the film or cause static electricity that will damage the film. When the film is completely rewound, you will no longer feel tension on the rewind knob.

Store the exposed film in a dry, dark container (such as a photo bag) or in its original canister until it is ready for developing. If your assignment requires you to shoot more than one roll of film, number the rolls directly on the canister using a china marker or laundry-marking pen.

INSPECTING AND MAINTAINING THE CAMERA

LEARNING OBJECTIVE: *Identify the correct method of inspecting and maintaining the 35mm single-lens reflex camera.*

The importance of caring for your camera cannot be overstated. The old saying, "Take care of your equipment, and it will take care of you," certainly holds true when it comes to photography. In the following text you will learn the basics of periodic camera inspection and maintenance, to include the lens, camera body and camera optics.

NOTE: You may be held liable for any damages while the camera is in your custody!

THE LENS

Remove the lens from the camera according to the manufacturer's instructions. Inspect the lens and check it for dirt, smudges, fingerprints and scratches. Remove dirt with a blower brush; eliminate smudges and fingerprints by gently wiping the glass with lens-cleaning tissue moistened with a few drops of lens-cleaning solution. Be careful not to oversaturate the tissue—one or two drops should be enough.

Minor scratches may not alter the performance of the lens, but you should bring them to the attention of your LPO or LCPO. However, deep scratches will probably affect the performance of your lens. In this instance, notify your supervisor and obtain a replacement lens. If you are not sure about the severity of a scratch, reattach the lens to the camera body, look through the viewfinder and focus on a subject. If any part of the field of view appears blurred or obscured, replace the lens.

Next, check the aperture control ring. The ring should click firmly into each position. Examine the focus ring. It should move smoothly, without interruption. Check the lens exterior for dents and other damage.

Finally, make sure the lens is mounted with an ultraviolet, haze or skylight filter to protect the front glass surface and its delicate antireflective coating.

THE CAMERA BODY

Inspect the camera body for dirt and defects. Use a blower brush to remove light dust and dirt; stubborn dirt can be removed with a silicon cloth or a soft chamois. **Do not use liquids to clean the camera body.** Liquid cleaners, including water, can damage the camera.

Check the back of the camera body and make sure it is light tight. While the back of the camera is open, conduct a shutter speed test to determine whether the camera has maintained its calibration. You do this by opening the shutter at the varying speeds from one second to 1/1000" (or faster). There should be noticeable differences at the slower speeds (1/1", 1/2", 1/8", 1/15", 1/30" and 1/60"). Inspect the back of the outer film carriage of the camera for nicks and warps. Examine the door hinge for looseness.

THE CAMERA OPTICS

Look through the viewfinder of the camera and focus on an object. If the field of view is blurred or

obscured and you know your lens is in good condition, you may have a dirty viewfinder.

If the mirror is dirty, clean it carefully, using a blower brush. **Do not use lens-cleaning tissue or fluid on the mirror.** If smudges remain on the mirror, consult your supervisor before taking the camera body to an authorized dealer or repair shop for professional cleaning.

OTHER IMPORTANT AREAS

Check the camera battery/internal light meter. A weak battery can affect your light meter reading, and ultimately, your photographs. Consult your instruction manual for further instructions.

Open the camera back and inspect the film chamber, rails, pressure plates, shutter curtain and take-up spool for dirt, film debris and other foreign matter. Use a blower brush to clean this area. Be careful not to press on the shutter curtain.

Inspect the neck strap for cracks and wear, especially at the pressure points (the clips that attach to the camera). In wet and humid climates, leather neck straps have a tendency to rot and should be checked daily.

Always store your camera in its case with the lens cap over the protective filter.

CAMERA ACCESSORIES

LEARNING OBJECTIVE: *Identify the most common 35mm single-lens reflex camera accessories.*

The difficulty of choosing camera accessories is knowing what is required and what is optional. There are many accessories photographers use in their day-to-day work, but we will only mention a few to give you an idea of what they are.

- Camera case
- Electronic flash
- Filters
- Lens and body caps
- Lens hoods

MOTOR DRIVES

Motor drives automatically wind-on or advance the film after each exposure. A motor drive will fire the shutter and advance the film for a preset number of exposures or work continuously. A motor drive simply

advances the film after each exposure is made manually.

CABLE RELEASE

A cable release is a device consisting of stiff wire encased in an outer flexible covering. It is used to trip a camera shutter without touching the camera itself. One end screws into the camera shutter release; the other end has a thumb-operated plunger.

CAMERA CASE

Several types of bags or cases are available for carrying your camera equipment. Some have a foam rubber lining that can be cut into the exact shapes of your equipment to protect and hold them firmly in place. Another type of case is called a gadget bag. It is usually made of leather or plastic and has either ridged or soft sides.

ELECTRONIC FLASH

The electronic flash is a high-voltage light source for illuminating the scene to be photographed. It produces a momentary flash of high-intensity light.

FILM HOLDERS

Film holders are light-tight containers for photographic film. They are used for positioning the film in the camera. Variations are called sheet film holders, film pack holders and roll film holders.

FILTERS

Filters are optical elements, such as glass, gelatin or plastic, dyed in a specific manner to absorb light of certain colors selectively, to emphasize or subdue certain objects and to improve the monochrome or natural reproduction of objects.

LENS AND BODY CAPS

Lens and body caps are protective covers that keep dust and moisture away from lenses and camera openings.

LENS HOODS

Lens hoods, or shades are used to keep strong sunlight from striking the front of the lens obliquely.

PHOTOGRAPHIC LIGHTING

LEARNING OBJECTIVE: *Identify the basic theories of photographic lighting in terms of outdoor lighting, existing light and electronic flash lighting.*

Light is the most important ingredient in photography. Light makes photography possible by reflecting off the subject, entering the camera and exposing the film.

Scientists tell us that light is produced in waves. In many respects the waves of light can be compared to sound waves. Sound waves vary in length and they register as different pitches; conversely, light waves register as different colors.

The intensity of light determines the brightness of the subject. The formula that determines this is the inverse-square law (fig. 11-10). It demonstrates that light decreases as the square of the distance increases. Becoming familiar with this law will help you use light more effectively during photographic assignments.

The light falling upon a subject from a source is called **incident light**. When incident light strikes a surface, it will change direction; this change is called reflection. If the surface is smooth, the reflected light is said to be specular; however, if the surface is rough, the reflected light is diffused. Most objects reflect back both types of light.

Reflection is an important characteristic of light. It is how our eyes can see objects and how film acquires a latent image.

In this section you learn how to take pictures using the following types of light:

- Outdoor
- Existing

Figure 11-10.—Inverse-square law.

- Electronic flash

OUTDOOR LIGHTING

Daylight and sunlight are not constant sources—they change hourly with the weather, seasons and latitude. The changes in daylight can radically alter the apparent shapes, colors, tones and forms of a scene. The color of sunlight changes most rapidly at the extreme end of the day. Strong color changes also occur during storms, haze or mist and on blue wintry days. The direction of the light changes as the sun moves across the sky. The shape and direction of shadows are altered, and the different directions of sunlight greatly affect the appearance of each scene.

The quality of sunlight depends on its strength and direction. Strong, direct sunlight is “hard”—it produces dark, well-defined shadows and brilliant highlights, with strong modeling of form. Sunlight is hardest on clear summer days at noon. Strong sunlight makes strong colors more brilliant, but weak colors pale. Sunlight is diffused by haze, mist and pollution in the air. This diffused or reflected light is softer; it produces weak, soft shadows and dull highlights. Directionless, diffused sunlight is often called flat lighting. It produces fine detail but subdues or flattens form. In weak, directionless sunlight, colors are muted—but strong, directionless, flat sunlight provides vibrant, well-saturated colors.

Frontlighting

The old adage about keeping the sun at your back is a good place to continue our discussion of outdoor lighting. The type of lighting created when the sun is in back of the photographer is called frontlighting (fig. 11-11).

This over-the-shoulder lighting was probably the first photographic advice you ever received. It may seem to be a universal recipe for good photography, but it is not. The case against over-the-shoulder lighting is that it produces a flattened effect, doing nothing to bring out the detail or to provide an impression of depth. The eyes see in three dimensions and will compensate for unhelpful lighting. However, a photograph is two-dimensional. To give an impression of form, depth and texture to the subject, you should ideally have the light come from the side or at an angle.

Sidelighting

As you gain experience with various types of outdoor lighting, you will discover that interesting effects can be achieved by changing the angle of the light falling on your subject. As you turn your subject, change camera viewpoint or wait for the sun to move,

Figure 11-11.—Frontlighting.
(Photo by JOCS (AW) Jon Gagné)

the light falls more on one side, and more shadows are cast on the opposite side of the subject. For pictures where rendering texture is important, sidelighting is ideal.

Look at a brick wall, first in direct front sunlight and then in sidelighting. Direct front sunlight will show the pattern of the bricks and mortar in a flat, uninformative way. But sidelighting will create shadows in every little crevice (fig. 11-12). The effect increases as the light is more parallel with the wall until long shadows fall from the smallest irregularity in the brickwork. This can give an almost three-dimensional effect to a photograph.

Sidelighting is particularly important with black-and-white photography, which relies on gray tones, rather than color, to record the subject. Shadows caused by sidelighting reveal details that can create striking pictures from ordinary objects that otherwise hardly would not be worth photographing in black and white. Anything that has a noticeable texture —like the ripples of sand on a beach, for example —gains impact when lighted from the side. Landscapes, buildings and people all look better when lighted from the side.

This principle also applies to color photography. Color gives the viewer extra information about the subject that may make up for a lack of texture in frontlighting, but often the result is much better when lighted from the side.

Figure 11-12.—Sidelighting.
(Photo JOCS (AW) Jon Gagné)

Backlighting

When the sun is in front of the photographer, coming directly at the camera, you have what is referred to as backlighting (fig. 11-13); that is, the **subject** is backlit. This type of lighting can be very effective for pictures of people outdoors in bright sunlight. In bright sunlight, when subjects are frontlighted, or even sidelighted, they may be uncomfortable and squint. Backlighting helps eliminate this problem. Backlighting may require the use of a reflector or fill-in flash to brighten the dark shadows and improve subject detail (fig. 11-14). Backlighting also is used to produce a silhouette effect.

When you use backlighting, avoid allowing sunrays to fall directly on the lens (except for special effects). Use a lens hood or some other means of shading the lens to prevent lens flare.

EXISTING LIGHT

Existing light photography, sometimes called available or natural light photography, is the making of pictures by the light that happens to be on the scene. This includes light from table, floor and ceiling lights, neon signs, windows, skylights, candles, fireplaces, automobile headlights and any other type of light that provides the natural lighting of a scene—except daylight outdoors. (Moonlight is considered existing light.) Existing light is that type of light found in homes, in offices, in the hangar bay, in the chapel, in

Figure 11-13.—Backlighting without a reflector.

Figure 11-14.—Backlighting using a reflector.

the club, in sports arenas and so on. Outdoor scenes at twilight or after dark are also existing light situations.

Photography by existing light produces pictures that look natural. Even the most skillfully lighted flash picture may look artificial when compared to a good existing light photograph. With existing light photography, the photographer has an opportunity to make dramatic, creative pictures. Existing light allows the photographer greater freedom of movement because he is not burdened with extra lighting equipment. Subject distance, when not using flash, has no effect on exposure, so you can easily photograph

distant subjects that could not otherwise be photographed using flash or some other means of auxiliary lighting. With existing light you can make pictures that you could not make with other types of lighting.

For example, flash may not be appropriate during a change of command ceremony or chapel service. Not only might the flash disturb the proceedings, but it may not carry far enough to adequately light the subject.

Fluorescent Lighting

Indoor scenes illuminated by fluorescent lights usually appear pleasing and natural in real life. However, color pictures of these same scenes will often have an overall color cast that makes them look very unnatural. Fluorescent light is deficient in red light and emits primarily blue and green light. Most color pictures made without a filter under fluorescent light also are deficient in red and have an overall greenish appearance. When it is used correctly, fluorescent light does have some advantages over other types of available light. A room illuminated by fluorescent lamps is usually brighter and more evenly lighted than a room illuminated by tungsten lamps. This higher level of light makes it easier to get enough exposure for your existing light photography and helps record detail that might have been lost in the shadow areas with other types of existing light.

When you are photographing people, fluorescent lighting often causes dark shadows under the eyes of the subject. This effect causes the eyes to appear dark and sunk in.

Nighttime, Outdoor Pictures

Outdoor night scenes usually include large areas of darkness broken by smaller areas of light from buildings, signs and streetlights. Pictures of outdoor scenes are quite easy to make because good results are obtainable over a wide range of exposures. The use of short exposures emphasizes well-lighted areas by preserving the highlight detail, while the shadow areas become dark due to underexposure. Long exposures help retain the detail of the dark areas, while highlight detail is lost as a result of overexposure.

Large, dark areas in night scenes will make it difficult for you to make accurate exposure meter readings from your camera position. You will get the best meter reading results when you take closeup readings of important scene areas.

At night you can make color outdoor pictures using either daylight or tungsten-type films. Pictures made on daylight film will have a warm, yellow-red appearance. Those made on tungsten film will have a colder more natural look. However, both films provide pleasing results so it is a matter of personal preference.

A good time for you to make outdoor night color pictures is just before it gets completely dark. At this time, some rich blue (or even orange) is in the sky. This deep color at dusk gives a dramatic background to your pictures. Neon signs, streetlights and building lights make bright subjects for your pictures.

ELECTRONIC FLASH LIGHTING

In situations in which there is little or no light available, a portable electronic flash unit is an invaluable piece of photographic equipment. With fast films and long exposures, you may be able to shoot existing light pictures—provided your subject remains still long enough. Although you can certainly get better lighting control with elaborate photographic lights, the simplicity and portability of electronic flash is unbeatable.

Electronic flash provides an excellent source of artificial light for exposing black-and-white and color daylight film. Light from an electronic flash unit (strobe) is characterized by its softness, short duration and color balance, approximating that of daylight.

When you measure the amount of light that actually reaches an object or scene, a numerical value is obtained that can be converted directly into a flash guide number. The numerical value is the light output rating of an electronic flash unit measured in beam candlepower-seconds (BCPS) or more correctly, effective candlepower-seconds (ECPS).

Every electronic flash unit is assigned a guide number as a measure of its light output or power. The higher the guide number, the greater the light output.

Correct exposure with electronic flash depends upon the following four factors:

- The power or light output of the flash unit
- The ISO speed of the film used
- The flash-to-subject distance
- The f/stop used

Shutter speed is not a factor since the time of exposure is governed solely by the duration of the flash.

Notice we always speak of **flash-to-subject distance**, never camera-to-subject distance. With all types of artificial illumination (the same as with sunlight), the only consideration is the amount of light reflected from the subject. The distance between the camera and the subject has no bearing on exposure. When the flash is used off the camera, the basic f/stop is still calculated with the flash-to-subject distance.

Automatic Electronic Flash Units

Most electronic flash units can be operated in an automatic exposure mode. An automatic flash unit eliminates the need to determine the correct f/stop for each flash-to-subject distance, providing the subject is within the flash distance range of the flash.

On the front of an automatic flash unit, a sensor reads the light reflected from the subject that is produced by the flash. When this sensor is satisfied as to the amount of light received, it automatically shuts off the flash. The closer the subject is to the lamp, the quicker the sensor shuts off the light.

Some automatic electronic flash units allow you to select two or more apertures to control depth of field. To determine an f/stop in the automatic mode, you can use the calculator dial located on the unit. When you match the indicator to an ISO film speed number on the dial (fig. 11-15), the f/stop to be used within a minimum and maximum distance is indicated. Once an f/stop is selected and set, it is a constant factor regardless of the flash-to-subject distance, providing it is within the flash distance range of the unit. This

Figure 11-15.—Exposure scale on a flash unit (automatic mode).

feature allows a photographer to move closer to or further away from the subject without having to calculate an f/stop for each change of flash-to-subject distance.

When the flash unit is in the manual mode, the f/stop must be changed every time the flash-to-subject distance changes. A scale on the flash unit (fig. 11-16) indicates the proper f/stop to use for the various distances. To determine the flash-to-subject distance for on-camera flash, focus on the subject and read the distance directly from the focusing ring on the camera.

Single Flash

You will produce the majority of your indoor photographs with a single flash unit. Numerous reenlistments, frocking and promotion ceremonies are conducted indoors where the lighting conditions are unfavorable for available light photography. There are various methods in which a single flash can be used to produce high-quality professional photographs that distinguish you from the amateur snapshooter.

On-Camera Flash

A flash technique commonly used is that of the flash unit attached to the camera, in synchronization with the shutter, and aimed directly at a subject. An advantage of having your flash unit attached to the camera is it gives you the chance to capture the unexpected—the truly candid shot. When spontaneity sparks the action and quick camera handling is a must, the fewer pieces of equipment you have to worry about or handle, the better. Rather than two pieces of gear (the camera and the flash), you have only one—the camera with the flash attached to it. However, this technique usually produces objectionable shadows behind the subject.

To help reduce the harshness of shadows, place some diffusion material, such as a white handkerchief, cheesecloth or frosted cellulose acetate, in front of the flash. Keep in mind that diffusion reduces the intensity of the light. Therefore, the exposure must be increased accordingly if you use the manual mode on the flash unit.

Off-Camera Flash

You will make some of your best flash pictures with the flash unit off the camera. When you hold the flash off the camera and above the lens, it will tend to throw the shadows down and behind the subject. This

Figure 11-16.—Exposure scale on a flash unit (manual mode).

is a good way to minimize distracting background shadows that occur when a subject is standing close to a wall. A flash held high above the lens, either left or right, makes the viewer less conscious of the flash illumination.

We are accustomed to seeing things lighted from above, and by placing the flash above the subject, it closely resembles the lighting of the sun or ceiling lights.

Light that is far enough off the camera to illuminate the subject from an angle produces modeling or roundness. This type of light creates the illusion of a third dimension—depth—and is more pleasing to the viewer than the two-dimensional flat effect you get with direct frontlighting. Angled lighting also is used to bring out the texture of a subject.

Bounce Flash

One of the best methods to illuminate a subject or scene with a single flash unit is to use **bounce flash**. There will be times when you will want a very soft light in order to lessen the tonal range between highlights and shadows and to soften harsh background shadows. You can achieve this soft lighting by bouncing, or reflecting the flash off a light-colored surface. By doing so you are changing the narrow spot of light from a flash unit into a wide, diffused area of light.

Most bounce flash pictures are made with the light directed at the ceiling, either above the photographer or above the subject, or somewhere in between. You can

produce a silhouette effect by bouncing the flash off the ceiling behind the subject. To accomplish this, aim your flash unit so most of the light bounced off the ceiling falls on the background behind the subject and calculate the exposure for the background.

For the flattest bounce light, try bouncing the light off a wall behind the camera. With this lighting you will have practically no shadows. Here you will have to calculate your exposure based on the flash-to-wall-to-subject distance.

“RED-EYE”

An effect that may appear with direct flash is “red-eye.” Red-eye occurs in pictures of people and animals when the flash is used close to the optical axis of the lens and the subject is looking at the camera. It is caused by light reflecting from the blood vessels at the back of the eye. The darker the room is, the stronger the effect will be because the pupils of the eyes will be dilated. Red-eye can be avoided easily by your moving the flash away from the lens optical axis. Also, you can minimize the effects of red-eye by turning up the room lights.

PHOTOGRAPHIC FILTERS

LEARNING OBJECTIVE: *Identify the purpose of photographic filters, the various filter designations, and the filters used in black-and-white and color photography.*

Filters, used mostly for feature photos, are used in all the various steps of the photographic process. Though often neglected in the shooting stage, the use of filters can tremendously enhance the final product in both black-and-white and color photography.

PURPOSE

The purpose of photographic filters is to alter the characteristics of light that reaches the light-sensitive emulsion. As light is transmitted through a filter, at least one of the following alterations occurs:

- The color of light is modified.
- The amount of light is reduced.
- The vibration direction of the light rays is limited.

To use photographic filters properly, you must understand the nature of transmitted light.

White light is composed of three primary colors: red, green and blue. A filter of a primary color will transmit its own color and absorb the other two; for example, a red filter looks red because it transmits red and absorbs green and blue, as shown in figure 11-17.

Secondary colors are mixtures of primary colors. Yellow, for example, is a combination of red and green. Because a filter passes its own color and absorbs others, a yellow filter passes red and green and absorbs blue (fig. 11-18).

In selecting a filter in black-and-white photography, you can use the color star in figure 11-19 to determine the effect of the filter on the gray scale of the negative and the final print. On the final print, the result will be that a filter will lighten its own color and the colors adjacent to it and darken its complement and the colors adjacent to its complement; for example, a green filter will lighten green (its own color) and cyan and yellow (adjacent colors). It will darken magenta (its complement) and blue and red (adjacent colors of the complement).

FILTER DESIGNATIONS

Some filters are designated by a descriptive name, such as neutral density, haze, polarizing and skylight. Color compensating and color print filters have yet another designation system.

The Kodak Wratten™ filter line uses a numbering system to designate its black-and-white filters, as shown in table 11-1. Also note in table 11-1 that filters in the first column lighten colors next to them, and opposite filters darken colors on the print. For example, a yellow-green No. 11 filter lightens subjects

Figure 11-17.—Characteristics of a red photographic filter.

Figure 11-18.—Characteristics of a yellow photographic filter.

Figure 11-19.—Color star.

that are yellow-green or yellow and darkens subjects that are violet. A No. 44 cyan filter lightens blue and blue-green and darkens light red and orange.

USING FILTERS IN BLACK-AND-WHITE PHOTOGRAPHY

Filters may be used in black-and-white photography for the following major reasons:

- To make the tones of gray in the final product conform more closely to the visual effects of colors in the original scene.
- To provide scenic contrast, such as darkening the sky so that clouds “stand out.” You can use a No. 15 or a No. 25 filter for this purpose.
- To lighten or darken a color to make it “disappear” or stand out in sharp contrast. An example of this could be photographing an old document that is written in blue ink and has yellowed with age. Here, a deep yellow filter would darken the blue writing, and, at the same time, lighten and possibly remove the yellow stain.

Whenever you use a filter, you must change the exposure. The amount of change depends on the sensitivity of the film to the colors absorbed by the filter as well as the quantity of that color in the type of light used. The effects of the filter in terms of exposure correction are given on the film data sheet as a filter factor.

The filter factor may be applied to the exposure by opening the diaphragm one f/stop each time the filter factor is doubled. Thus a factor of two requires that the diaphragm be opened one f/stop larger than is needed for correct exposure without a filter; a factor of four calls for two f/stops, a factor of eight for three f/stops, and so on.

Table 11-1. —Kodak Wratten™ Filters

Filter Color and Number		Filter Color and Number	
Deep Red	29	Bluish Green	65
Red	25	Bluish Green	65
Light Red	23A	Cyan	44
Orange	21	Cyan	44
Deep Yellow	15	Blue	47
Yellow	8	Deep Blue	47B
Yellow-Green	11	Violet	34A
Yellow-Green	13	Violet	34A
Green	58	Magenta	33
Green	61	Magenta	33

Kodak Wratten™ is a trademark of the Eastman Kodak Company

An easy formula for determining exposure correction when you are using a filter is to divide the film speed by the filter factor and use the result as a corrected film speed on your exposure meter. As an example, when you use a black-and-white film with an ISO of 400 and a No. 11 filter (filter factor four), divide four into 400 and use the result, 100, as the film speed on the exposure meter. When using this method, make sure you return the meter dial to the correct film speed after using the filter.

FILTERS FOR COLOR PHOTOGRAPHY

Problems associated with color materials are quite different from those encountered with black-and-white materials. In color photography, the main problem is achieving correct color balance. The principal factor involved is the color temperature of the light source being used to illuminate the subject. This provides a natural appearance to the final product. Filters for color photography are classified as light balancing, conversion and color compensating.

Light Balancing Filters

Light balancing filters come in two series (not to be confused with a series that indicates physical size): the series 81 (yellowish filters) are used to lower the color temperature of a light source, and the series 82 (bluish filters) are used to raise the color temperature of light from a light source. Both series are used when a tungsten light source is used with color film.

Conversion Filters

Conversion filters are used in color photography when a **significant** adjustment of an exposing light is required to convert the color quality of the exposing light to the color temperature for which a film is balanced.

Conversion filters generally come in two series. The 80 series of filters are blue in color and convert tungsten light to color qualities acceptable for use with daylight film. The 85 series of filters are amber in color and convert daylight to color qualities acceptable for use with tungsten film.

The correct filter to use for a given situation with a given film can be determined by reading filter and film data sheets. If you are in doubt, seek help from your shop or base imaging facility.

Color Compensating Filters

Color compensating (CC) filters are used to adjust the overall color balance obtained from color film, particularly slide film. Without the use of color compensating filters, improper color cast can result.

For cameras, CC filters are normally used to color balance the light from sources, such as fluorescent, tungsten, and mercury-vapor lights, and the “bounce” light reflected from colored surfaces. They are also used to balance lighting effects under unusual circumstances (such as underwater lighting). These filters can be used to compensate for a known color deficiency of an unexposed color film. They also can be sandwiched (layered) when mounting a color transparency to compensate for an off-color hue.

SPECIAL-PURPOSE FILTERS

Some of the special-purpose filters you will work with include the following:

- Neutral density
- Haze
- Polarizing
- Skylight

Neutral Density Filters

Neutral density (ND) filters reduce the amount of light passing through a camera lens without changing the reproduction of colors in the scene. These filters are nonselective in their absorption of colors of light and therefore uniformly reduce the various colors of light in the spectrum. Thus white light and colored light are transmitted through a ND filter with only the **intensity** of the light being affected. These filters can be used with both black-and-white and color film.

ND filters are gray in appearance. These filters may be needed for pictures of a brilliant subject in bright sunlight. When you have set the fastest shutter speed and the smallest f/stop and still cannot take the picture without overexposing the film, you can use a ND filter to further reduce the exposure.

Haze Filters

Suspended in the earth’s atmosphere are minute particles of vapor and dust that cause a veil-like appearance called haze. This haze is most apparent in distant scenes. Haze is the result of sunlight being scattered by minute particles of matter that are present

in the air. The amount of haze can vary due to atmospheric conditions. Haze should not be confused with mist, fog, smog, smoke or clouds. These conditions also can produce a veil-like appearance but filters have no effect.

When sunlight is scattered, green and red light also are scattered by the ever-present haze, but not nearly as much as ultraviolet radiation, violet and blue light.

Penetration of the haze is possible when filters are used to absorb scattered sunlight. A haze filter is any filter that absorbs atmospherically scattered sunlight. This includes contrast and correction filters. When contrast and correction filters are used for haze penetration, they may be considered special-purpose filters. Although contrast filters can be used for cutting haze, these filters affect the gray tone rendering of colored objects. The contrast and correction filters that absorb the shorter wavelengths are the most effective. The recommended contrast and correction filter colors, in the order of greatest to least effective, for haze penetration are as follows:

- Red
- Orange
- Yellow
- Green

The use of an infrared sensitive black-and-white film with an infrared filter provides the greatest haze penetration of all.

Polarizing Filters

Polarizing filters look like gray neutral density filters. However, their effect becomes apparent when you look at the blue sky through a polarizing filter while rotating it. As you rotate the filter, the sky appears to get darker, then lighter.

Polarizing filters are used in black-and-white and color photography for the following reasons:

- To reduce or eliminate unwanted reflections (glare) from nonmetallic surfaces, such as glass and water
- To effect exposure control (similar to ND filters)
- To reduce the effects of haze
- To darken the blue-sky image in both black-and-white and color photography

- To increase color saturation in a color photograph without altering the hues of image colors

There are a number of different polarizing filters. However, there are only two main types: one type fits over the camera lens, and the other is designed to be used over a light source. Since they do not affect color, polarizing filters and screens may be used for both black-and-white and color photography.

Skylight Filter

A skylight filter adds warmth to a scene recorded on color transparency film by absorbing ultraviolet radiation. It does this by reducing the bluish cast prevalent in distant scenes and in scenes photographed on heavily overcast days or in open shade. A skylight filter is light pink in color.

EXPOSURE CALCULATION

LEARNING OBJECTIVE: *Identify the components used to calculate a photographic exposure.*

When you click the shutter, a series of events occur inside the camera. The shutter opens and closes, and light passes through the lens of the camera onto the sensitized emulsion (film), forming a latent image. The emulsion will eventually yield a record of what the camera saw at the moment of exposure. This series of events will yield a satisfactory photograph, in a technical sense, only if the exposure was correct.

You must compute exposure to make sure that the amount of light reaching the sensitive emulsion is sufficient to record the image. Exposure depends on the sensitivity of the photographic emulsion to light and on the brightness reflected by the original subject. Because you usually desire to record the whole range of tones between the brightest and darkest parts of the original scene, you will have to adjust your exposure accordingly.

The same exposure can be given to a certain subject by using various combinations of lens openings and exposure times — a wide opening and short time of exposure may allow the same total amount of light to reach the photographic emulsion as a small opening and a long exposure time. At the moment, your consideration of the other factors involved in exposure, such as image movement, depth of field and the use of filters, is unimportant. After you

have decided upon the correct total exposure necessary for a given subject at a given time, you can modify the lens opening and shutter speeds later as you desire for specific results.

Incorrect exposures will ruin more of your photographs than any other technical error, yet accurate exposure is relatively simple. By reading and using the exposure guides contained in the film data accompanying your film, you can expect good results most of the time. However, accurate exposures using daylight or tungsten light sources can only be obtained by the correct use of an exposure meter.

An important factor for you to remember is that no light meter, camera, film or manufacturer can guarantee the correct exposures that good photography demands. The only guarantees are your awareness and practice of the exposure theory and practical meter techniques. Good exposure techniques are efficient and simple. Your having the knowledge of exposure techniques frees you from the stumbling block of exposure determination so you can concentrate on taking pictures, and it simplifies the subsequent developing and printing process.

THEORY

The term *exposure*, while having different meanings at different times, is most often used by photographers to indicate a certain combination of shutter speed and lens aperture. In this case, the shutter speed denotes the length of time the shutter is “open,” allowing light to pass through the lens to strike the film.

As stated earlier, various combinations of lens aperture and shutter speed can yield the same exposure. The correct determination of camera exposure is the object of all exposure tables, charts, calculators and meters.

In any given photographic setting a variety of light will be reflected, since the brightness of various objects will reflect varying densities of light. Therefore, the exposure must be adjusted to produce the correct range of densities.

The result of exposure and development of film is very similar in many ways to that of rain falling on a light-colored concrete sidewalk. When the rain begins, only a few drops fall. The cement is darkened at only a few spots. As the rain continues, the cement becomes darker and darker, until it is uniformly wet and dark. Continued rain will then cease to cause any more changes in the color of the cement sidewalk.

You have experienced differences in the intensity of rain showers. At high intensities, much water comes down in a unit period of time, such as one minute. At low intensities, the amount of water is much smaller. As a result, you could get the same total amount of water within varying periods of time, according to the intensity of the rain. The total amount of rain recorded is equal to its intensity multiplied by the time during which it fell. The effects with light are very similar. Exposure is the amount of light falling on a unit area of the film or on a unit area of photographic paper. The intensity is the amount of light falling on this unit area during the exposure time. Thus the equation for exposure is as follows:

$$\text{Exposure} = \text{Intensity} \times \text{Time} (E = I \times T)$$

Another similarity between light and rain on a sidewalk is in the blackening effect. With light the blackening (during development) increases with the exposure received by the sensitive film emulsion. The photographic lens and shutter assembly should be regarded as a device that controls the camera exposure received by the light-sensitive film emulsion inside the camera.

The aperture of the lens diaphragm controls the intensity of the light, and the shutter controls the time of exposure. Since a photographic reproduction of the original scene contains a range of tones of different brightness, a corresponding range of photographic exposure is given to the sensitized emulsion.

FILM LATITUDE

A negative is said to be correctly exposed when it gives a satisfactory rendition of detail in both the deepest shadows and brightest highlights of the scene or subject. Fortunately, in many cases, there is more than a single exposure that will produce this result — there is a wide range of possible exposures within which satisfactory tone separation is possible. The “minimum” satisfactory exposure is one in which good tone separation is just attained in the deepest shadow areas. The “maximum” satisfactory exposure is one in which detail is just retained in the brightest highlight. Any additional exposure will cause this highlight detail to become flattened out or “blocked up.”

The range between these two exposures is known as latitude. This latitude may be narrow or wide, depending on the subject matter, lighting contrast, type of film and degree of development of the negative. In general, the black-and-white films you will be using have a greater margin for error than color films.

Ignoring the influence of development for a moment, a softly lighted scene composed of objects that are, themselves, fairly uniform in tone will allow a wide range of possible exposures that will produce a satisfactory rendition on the negative. This is caused by the narrow range of tonal values from highlight to shadows in the subject. On the other hand, a brilliantly lighted scene composed of a variety of tones, from jet black to snow white, may take up the entire usable range of the negative scale. Therefore, the exposure required for the proper rendition of the entire range of tonal values in this scene may be quite critical.

In addition there are many scenes, such as interiors with sunlight coming through a window, that have a range of brightness so wide that no single exposure can produce both highlight and shadow detail in a black-and-white negative. When you increase exposure and reduce the amount of development, almost any ordinary extreme of brightness range can be accommodated on black-and-white film.

FILM SPEED

The sensitivity of black-and-white and color film for still-camera use is also called the film speed, the ISO speed or simply the ISO. Earlier in this chapter, we pointed out that “ISO” is an acronym for International Standards Organization, a federation of all national standard bodies of the world, which has approved a uniform set of film-speed standards. These standards call for a universal expression of both arithmetic and logarithmic values with the ISO designation.

Until early 1983 the emulsion speeds of still-camera film were expressed in ASA values (which are arithmetic) or in DIN values (which are logarithmic). ASA values were determined according to standards published by the American National Standards Institute, formerly American Standards Association from which the designation ASA came. The DIN values reflected the German standards established by the Deutsche Industrie Norm.

Film speed is determined by the manufacturer according to the ISO standards. It will generally look like this:

ISO 100/21°

The number immediately following “ISO” is the ASA equivalent. It indicates that the speeds progress arithmetically, and any film marked ISO 100 has the same sensitivity as any other film marked ISO 100 — it is twice as fast as film marked ISO 50 and is half as fast

as film marked ISO 200. The number with the degree symbol (°) is the DIN equivalent.

The arithmetic speed number is intended for exposure meters or cameras marked for ISO or ASA speeds or exposure indexes. The logarithmic speed is intended for exposure meters or cameras marked for ISO or DIN settings.

FILM TYPES

Photographic films (and papers) are composed of two basic parts: the emulsion and the base, or support. The emulsion is the light-sensitive portion of a film or paper that records the image. The emulsion contains the silver halides and any special sensitizing dyes suspended in a binder of gelatin. The gelatin holds the silver halides evenly dispersed and prevents action by a developer until the silver halides have been made developable either by exposure to light or chemical action. The gelatin also acts as a sensitizer for the silver salts.

In photographic films and papers, the main purpose of the base is to support or hold the emulsion in place. Depending on how the recorded image is to be used, the base or support may be transparent or opaque. A transparent base is used for transparencies viewed by transmitted light and for negatives printed with transmitted light. An opaque base is used for prints that are viewed by reflected light.

The latest state-of-the-art in light-sensitive materials used in photography is the use of the electronic medium. Still video disks do not contain an emulsion or a base. When video mediums are used, light is converted to electrical impulses, and these impulses are stored magnetically on a tape or disk. Since it is the camera itself that converts the light to electrical impulses, the recording medium and all stages of the photographic process can be carried out in normal room light.

Black-and-White Film

The characteristics and use of black-and-white film depends largely on the actual construction of the emulsion. These characteristics include the following: the degree of sensitivity to light, response to various colors of light (color or spectral sensitivity), contrast, exposure latitude, emulsion latitude and emulsion definition.

There are many types of black-and-white films available. Each differs from others in one or more

characteristics. You should become acquainted with the characteristics of films. This knowledge is helpful in selecting the film most suitable for each photographic assignment.

Color Negative Film

A color negative film records a scene in image densities opposite to the brightness of objects in the scene, the same as a black-and-white negative film. Color films can be recognized because they contain the suffix “color,” such as Vericolor, Kodacolor and Fujicolor. These color films are used when a print is the final product. Most color negatives (except for color film used for aerial photography) has an orange mask incorporated in it. This orange mask increases the color separation, which reproduces colors more accurately in the final print.

During development, colors that are complementary to the color in the original scene are formed in the emulsion. For example, a red object in the scene is recorded as cyan in the negative. A combination of yellow, magenta and cyan record all the other colors that we see in the scene. Color dyes in the emulsion layers control the colors of light passing through the color negative.

To produce color prints or color transparencies, you can print color negative film images on color positive materials such as color paper and color print film. Color negatives also can be printed on a special panchromatic black-and-white paper to produce black-and-white prints.

Amateur and Professional Color Films

Much of the color film used in the Navy is manufactured by the Eastman Kodak Company. Kodak markets color films for both professional and amateur photographers. Color films intended for use primarily by professionals are identified by the word professional in the name — for example, Kodak Vericolor III Professional Film, Type S (VPS).

Both professional and amateur films have similar color quality, sharpness and granularity characteristics. They also have emulsions made up of many different chemicals that tend to change slowly with time. From the day they are made, all color films begin to change, and as the films age, their color balance changes.

Amateur films are manufactured to age and reach a peak color balance much later than professional films.

The manufacturer allows for the time amateur film will be in storage, on the store shelf, and in the camera before it is developed. The ISO speed assigned is adequate for calculating exposure for normal picture-taking situations.

Professional films are manufactured so they are very near their optimum color balance at the time they are shipped from the factory. These films should be kept refrigerated or frozen until shortly before use. Refrigeration keeps the film near the optimum point until used and provides the photographer with confidence in consistent results. Precise film speeds are provided for professional films. The film is intended for prompt processing to prevent any significant shift in color balance after exposure.

MEASURING EXPOSURE

The quantity of light can be measured in several ways. The most accurate method is the use of exposure meters. Photographic exposure meters are designed to be sensitive to light in the same manner as panchromatic film. Therefore, an exposure meter reading can be assumed to be valid under any visible lighting condition. Several types of hand-held meters are available. Some measure incident light; some measure reflected light. Another line of light meters measure light only within the sensitivity range of the human eye.

However, for news photography and most other requirements of a Navy Journalist, the built-in light meter described earlier in this chapter should more than satisfy your needs. This battery-powered meter, which measures reflected light, works automatically (unless you use the manual setting) to give you the correct exposure. When used manually, the built-in meter functions the same as a comparable hand-held meter and allows you to make whatever adjustments you prefer to achieve stylized or creative photographs. Except in cases involving special motion picture film lighting and portrait studio work, the hand-held exposure meter has virtually been replaced by the built-in camera meter.

Before using any exposure meter, read the instruction book that comes with it to make sure that you use it correctly. The readings from an exposure meter, and the accuracy of the meter itself, are wholly dependent on the method used.

CAMERA SETTINGS

When the photographer knows the sensitivity of the film and the amount of light available, the user determines the settings on the camera that will give the film a correct exposure. The settings are the f/stops and the shutter speed. Together, they control the total amount of light allowed through the camera to form the latent image on the film.

F/stops can range from f/1.4 (most amount of light) to f/22 (least amount of light). The f/stop system (factorial system) is always read as a whole number, not as a fraction or ratio.

Full stops in the English system of f/stops are as follows: 1.0, 1.4, 2.0, 2.8, 4.0, 5.6, 8, 11, 16, 22, 32, 45, 64, 90 and so on. Notice that the number doubles for each two-stop decrease in size. Slight optical corrections are made for f/11 and f/45. This may seem confusing at first, but knowledge of the f/stop system is necessary to compute optical formulas used by advanced photographers. It is necessary to know that each marked f/stop on a lens, except its widest aperture, is usually a full stop — that is, it admits one-half or twice the amount of light as the adjacent stop, and the larger the number, the smaller the aperture. At first, it is perhaps easier to think of the f/stops in terms of fractions; 1/8 is larger than 1/11 which is, in turn, larger than 1/16.

Lens apertures can be set between marked f/stops. You could match information on the exposure calculation dial of an exposure meter. For example, if the light meter suggests an exposure of 1/125" at f/9.5, you could set the camera at 1/125" at f/8, allowing the film latitude to cover the difference, or at 1/125" with the lens aperture midway between f/8 and f/11, which would be more accurate (fig. 11-20).

Shutter speeds control the duration of time that light is allowed to pass through the lens aperture to the film. Shutter speeds are usually marked on the camera as the reciprocal of the fraction of a second that the shutter remains "open" (one is 1/1 or one second, two is 1/2 or one-half second, four is 1/4 or one-quarter second and so on).

Standard shutter speeds are 1", 1/2", 1/4", 1/8", 1/15", 1/30", 1/60", 1/125", 1/250", 1/500", 1/1000" and 1/2000".

f/Stop-Shutter Speed Combinations

With today's cameras offering you the opportunity to use automatic settings, you could just concern

Figure 11-20.—Comparison between aperture, f/stop and relative exposure.

yourself with the f/stops of the camera and let the automatic shutter speed controls of the camera do the rest. However, should you choose to work with your camera in manual mode, you must understand the relationship between the f/stop and shutter speed.

Shutter speeds are indicated so that each marked shutter speed admits one-half or two times the adjacent marked speed. Since both the lens aperture and shutter speed represent "full stop" changes in exposure, either can be moved as long as the other is moved a similar number of stops to compensate. A basic exposure of 1/125" at f/16 can be changed to 1/500" (two stops less light transmitted) at f/8 (two stops more light transmitted), and the result will be the same total amount of light transmitted to the film.

Shutter speeds cannot be set between marked "stops." If an exposure is calculated to be 1/40" at f/8, using the closest shutter speed available on your camera, 1/30" or 1/60" will not result in an exposure error because of the exposure latitude of the film. An alternative is to set the shutter speed and an equivalent "half-stop" of lens aperture, such as 1/30" at f/9.5, or 1/60" at f/6.3.

With a selection of possible combinations, which should be used? Does it matter which is used? Why does the manufacturer put so many combinations on the camera?

Before these questions are answered, you must understand the correlation of lens apertures and shutter speeds. Think of the lens aperture as a water pipe (the larger the diameter of the pipe, the more the water can flow). Extending this further, think of the film

sensitivity in terms of a bucket that has to be filled and the light intensity as the water pressure.

If a bucket can be filled in 1/30" with a pipe 8 square inches in area, how long would it take to fill using a pipe 4 square inches in area? Obviously, twice as long —1/15". If the exposure is calculated at 1/30" at f/11, how long an exposure is required at f/16 (the aperture one-half the area of f/11)? The answer is 1/15".

What happens if the water pressure increases? It takes less time to fill the bucket. If we use a larger bucket (lower ISO film speed), it takes more water (exposure) to fill it.

Shutter Speed Considerations

Generally, the shutter speed is chosen according to the amount the subject moves or how much of the movement you desire to show. If the subject moves slowly, a slower shutter speed can be used; if the subject moves rapidly, a faster shutter speed must be used to stop the movement and prevent blurring the image. Movement of the camera and photographer also must be considered. Therefore, the use of a tripod or similar brace is advisable when using a shutter speed slower than the reciprocal of the lens focal length; for example, 50mm lens (1/60"), and 200mm lens (1/250").

To stop the movement or action in a picture, you must consider the following three factors:

- The relative movement of the subject
- The subject's direction of movement
- The camera-to-subject distance

THE RELATIVE MOVEMENT OF THE SUBJECT.—The faster the movement, the faster the shutter speed required. The term *relative movement* is used because if the motion of the subject is followed, that is, the action is "panned" with the camera, a slower shutter speed can be used than if the camera were held stationary.

THE SUBJECT'S DIRECTION OF MOVEMENT.—A subject traveling at a right angle to the camera/lens axis requires a faster shutter speed than one traveling at a diagonal. Conversely, a subject moving toward or away from the camera, parallel to the lens axis, can be "stopped" with a slower shutter speed than movement in other directions (fig. 11-21).

SUBJECT	DIRECTION		
	↓	↘	→
Pedestrian (4 MPH)	1/60	1/125	1/125
Tractor (8 MPH)	1/125	1/250	1/250
Runner (12 MPH)	1/125	1/250	1/500
Sports, general (15 MPH)	1/250	1/500	1/1000
Horse, galloping (20 MPH)	1/250	1/500	1/1000
Automobile (35 MPH)	1/250	1/500	1/1000

Figure 11-21. —Slowest shutter speeds necessary to stop action.

THE CAMERA-TO-SUBJECT DISTANCE.—

The closer the action is to the camera, the faster the shutter speed must be. A car traveling 60 miles per hour across the lens axis at a distance of 100 feet would be "stopped" by a shutter speed of 1/1000" (or perhaps 1/500"). However, if the camera-to-subject distance were increased to 500 feet, the action could be "stopped" with a shutter speed of "1/250" or "1/125." If the car was a half-mile away, 1/60" should be sufficient to stop the movement.

DEPTH OF FIELD

Selection of a f/stop is done mainly for the desired depth of field. "Depth of field" is defined as the distance between the nearest and farthest points of acceptable sharp focus of the scene photographed (fig. 11-22).

Control of the depth of field is a valuable tool in photography. Depth-of-field charts are given in all camera instruction books as well as in photographic

Figure 11-22. —Depth of field.

reference manuals, but many photographers fail to use them to their own advantage.

Simply stated, depth of field increases as the focal length of the lens decreases (a shorter focal-length lens is used), as the lens aperture decreases (gets smaller in size) and as the distance focused on (focal point) increases, or both. Inversely, depth of field is less for long-focal-length lenses than for short-focal-length lenses, is less for wider apertures and is less for shorter lens-to-subject distances.

A peculiarity of the term *depth of field* is that it is usually used to define a condition of maximum depth of field; and when the depth of field is shallow or purposely restrictive, the term *selective focus* is used. Selective focus is merely “selecting” a depth of field that will satisfy a requirement to have the foreground, background, or both, not in sharp focus. The use of selective focus to make the main subject stand out in the picture by being “sharp” while the rest of the image area is blurred is a good technique for gaining subject emphasis.

The importance of proper focus and shutter speed cannot be overemphasized. Incorrect focus, subject movement, camera movement, improper use of depth of field and so forth, can result in a blurred image on the photographic negative that cannot be corrected in any way. Film latitude can take care of minor errors in the exposure, but there is no latitude for focus and stop action. An image is either in focus or out of focus; action is either stopped or blurred.

DIRECTING PHOTOGRAPHIC SUBJECTS

LEARNING OBJECTIVE: *Identify the methods used in coordinating individual and group photographs.*

One of the most difficult tasks of photographing people is directing them. Since you are the only person who can see what the picture will look like before it is taken, you must take responsibility for “the pose.”

INDIVIDUAL PICTURES

As a Navy Journalist you will take pictures of individuals for a multitude of projects, such as news releases, familygrams and cruisebooks. Therefore, you should be familiar with the methods used to direct photographic subjects.

One way to make directing and posing easier is to give your subject an object to handle. Do not tell him to “just stand there,” as though in a vacuum, with nothing to do. Men and women can hold a book, binoculars or a tool used in their work. Children will do fine with a doll or model airplane.

Another strategy is to give your subject something to lean or sit on. Use a chair, stool, post or tree.

If you use props in your individual photographs, make sure you do your homework. For instance, do not photograph a Gunner’s Mate holding a 3-inch shell in front of a 5-inch gun mount.

Eyes are very important when photographing people. When the subject’s eyes look straight into the camera, a strong and immediate impact is created that attracts the viewer’s interest. When the eyes are directed away from the camera, the effect is less explicit and has more of an ambiguous quality. Decide on the approach that is best for your photograph and direct your subject appropriately.

Finally, you must be in charge of the situation. It is up to you to tell the subject what to do, how to do it and when to do it. This applies to a vice admiral as well as a seaman.

Many people are nervous and self-conscious in front of a camera. They try to look their best, and in doing so often present a stilted expression or pose. It is your job to give directions regarding their pose. It is also your responsibility to make sure that coat sleeves are pulled down and wrinkles are smoothed out. Make sure the subject’s hat is set at the proper angle. If you ignore these potential problem areas, your photograph will ultimately suffer.

GROUP PICTURES

Occasionally you will receive an assignment to photograph a group of people. There is added difficulty when working with a number of people at one time. You should consider each person individually, but you should also consider each individual as he relates to the entire group. Every precaution should be taken to make sure each person is shown clearly, and interest is not drawn to one person by some awkward pose or expression.

There are two general types of group pictures—formal and informal. Both are covered in the following text.

Formal

A formal group is one in which several people, uniformly dressed for the occasion, are seated or standing in as nearly the same pose as possible. Each member is placed in approximately the same relative position so that attention is not drawn to one person (fig. 11-23).

A formal group of about five people can be composed to fill the picture area very nicely. When six to 10 people are being photographed in a group, arrange them in two rows. For larger formal groups, arrange the people in as many rows as necessary to fill the frame. Avoid stringing out one long, narrow line of people across the frame.

When a large group is formed into three or more rows, you must devise some method to prevent the rear rows from being blocked from view. Furthermore, to compose the picture properly and fill it from top to bottom, you should have each row higher than the preceding one. One method is to arrange the group on the steps of a building, bleachers or terrace, so each row is higher than the preceding one. On level ground the first row can be seated, the second standing, and the third standing on benches. Another method which you can use in combination with the first is to elevate the camera so that it is pointing down at an angle on the group. This method is useful as an aid in composing and filling the picture area. A higher camera angle can be useful in eliminating an undesirable background.

Customarily, in a formal group, the highest-ranking person is located in the center of the first row and other members of the group arranged alternately to the right and left, according to grade. When all members of the group are the same grade, arrange them according to height, with tall individuals either in the center or at the ends, or occupying the rear rank.

Informal

The informal group is intended to depict some action or tell a story about the individuals. Although

Figure 11-23. —Formal group photograph.
(Photo by Mamie Burke, DoD)

the position and pose of each member is carefully planned, the results must appear casual and realistic (fig. 11-24). Members may be seated, kneeling or standing in a variety of positions and do not have to look in the same direction.

One of the most important factors in group photography is arranging people to obtain the best possible composition. Regardless of the number of people in a group, they should be situated to fill the picture and provide the largest possible image size of each person. One exception to this general rule is when the importance of the background is equal to or greater than the group itself. This often occurs with an informal group when the picture is actually intended to emphasize some object or piece of equipment, rather than the individuals. In this case, locate the camera for the best composition of the object; then arrange the people in the picture to enhance the story being told.

As with individual pictures, you must stay in charge. If you relinquish control, you will have a hard time getting everyone to look at the camera at the same time. Talk to the group and give them your instructions. Make sure your equipment is ready so you do not waste time and lose the group's attention.

STILL DIGITAL PHOTOGRAPHY

LEARNING OBJECTIVE: *Recognize the basic process of still digital photography.*

Photographic technology is constantly evolving. The introduction of **still digital photography** in recent years has already changed the way most photographers

Figure 11-24.—Informal group photograph.
(Photo by Scott Davis, DoD)

take and process pictures, and the way that newspapers and other publications use photographs.

Still digital photography, as the name implies, allows you to take photographs and store them electronically (digitally) in a specially manufactured camera. You can then process the photographs using digital photographic software installed on the hard disk drive of your computer. This software will allow you to view, crop and color correct your photographs. When you are finished, you may “output” the photographs to the hard disk drive (for long-term storage), a modem (for transmitting to another computer) or a printer to produce color prints, transparencies or negatives. The still digital photography process is shown in figure 11-25.

While it is common to scan regular film images and prints into your computer for digital handling, the real advantages come when using a digital camera. The full potential of digital photography, including the speed, manipulation advantages and minimum of waste apply when creating images with a fully digital system. While top-of-the-line digital cameras are more expensive than regular SLR cameras, in the long run, the savings pay for the start-up costs.

DIGITAL VS. TRADITIONAL PHOTOGRAPHY

Traditional photography starts with a regular camera and a silver or dye based film. After the film is exposed, it is removed from the camera and processed in up to seven (for slides) different chemical baths, washing, and then drying. Once the film is dry, prints can be made. By projecting the negatives or slides on to photosensitive paper and again processing using chemicals, prints are made.

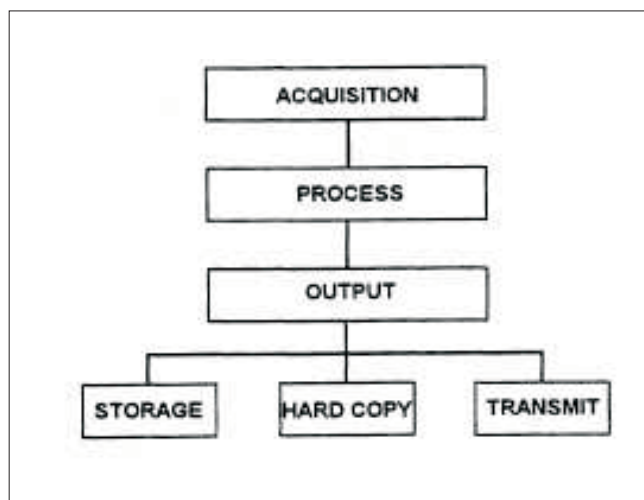

Figure 11-25.—The still digital photography process.

This traditional process has several distinct disadvantages. First, is the amount of waste. If only one image is needed when shooting a roll of film, an entire roll of film must be used. This can become costly. Second, is the amount of time it takes. The processing and print making steps take a minimum of about 15 minutes, using expensive automated processing equipment. Slides take at least an hour to process. Third, are the hazardous chemicals involved in the process. While not extremely dangerous, most photo chemicals are at least mildly caustic, and some are rather hazardous. Last is the storage and disposal of the chemicals.

Digital technology does away with many of these problems. Images are taken with a standard camera that has a Charge Coupled Device (CCD) where film normally would be located. After images are taken, they can be immediately previewed on a computer. To transfer an image to the computer, just double click on the file. There is no waste when only a few images are required. There are no chemicals to store or dispose of. Not only are these disadvantages eliminated, but the entire process is much faster and you have the benefits of being able to electronically edit the photos before printing using one of several photo software programs available on the market.

DIGITAL CAMERA

There are two types of electronic cameras: still-video and digital. A still-video camera is similar to a video camera without the tape storage drive. Still-video cameras take analog images in two passes, first the even rows, then the odd rows. This process is called interlacing, and can result in fuzzy images with fringing on high contrast scenes. To accommodate this interlacing, the still-video camera has smaller light sensitive cells than full-frame CCD's used in digital cameras.

Digital cameras are designed to provide a digital image from the ground up. Since digital cameras do not require the extra circuitry needed to interlace the image, the light-sensitive cells can be larger and closer together resulting in high quality images (fig. 11-26).

One of the main differences between traditional film based cameras and digital cameras is how the image is stored once the photo has been taken. With a film-based camera, the image is stored on film in the form of a latent image. Each roll of film can only hold a certain number of images, and when all the images are used you must insert a new roll of film. Digital cameras

Figure 11-26.—The digital camera.

work on a slightly different principle. After the image is exposed, the digital image is written to built-in memory devices.

There are several different types of storage devices. The DCS 200 has a built-in hard disk that can store as many as 50 images; some digital cameras can store even more. The drawback to a built-in drive is that when the drive is full, you must connect the camera to a computer to download or delete images before you take more photos.

More advanced digital cameras contain removable PCMCIA (or “PC”) cards. This card is about the size of a small stack of credit cards, and has a mini hard disk inside. This hard disk can be various sizes up to about 230 Mb, capable of taking about 135 images per disk. The benefit of using a removable PC card is that once the card is full, another card can be immediately inserted.

Some of the less expensive digital cameras store images in battery powered internal memory chips called Erasable Programmable Read Only Memory (EPROM). The disadvantage to this memory option is that you must download the images when the memory is full. Also, if the batteries die, you will lose the images.

The Navy uses a wide variety of digital cameras, depending mostly on the needs of the command. If the camera is to be used simply for recording command activities and special events, a digital camera with a zoom and flash will meet the command’s needs. These cameras are relatively affordable and reliable. Some research should be conducted, however, to ensure that you get the camera that meets your needs.

For more professional photography, there are many models and styles available that will capture not only still images, but video as well.

Camera techniques and feature photography are covered in chapter 12.

PHOTO JOB ORDERS

LEARNING OBJECTIVE: *Identify the purpose of the photo job order and list the required photo job order information.*

In areas where Navy imaging facilities are located, one of the easiest means of getting photographic coverage is by properly filling out an audiovisual job order form. The title of the form may change to include other services, but you should have an understanding of the purpose and basic information needed to fill out the request for services properly.

A job order serves as the authority for requested work, the record of the imaging facility and its receipt. It accompanies the work being performed through every phase of the photographic process.

To use the job order successfully, you should develop a good understanding and relationship between your unit and the imaging facility.

In submitting a job order, all information pertaining to the job should be recorded to avoid confusing the photographer performing the actual work. The job order information you must provide includes the following:

- Name of your activity
- Your activity job number
- Job security classification
- Number of views needed
- Size and finish of prints
- Priority and date required
- Location of work
- Name and telephone number of person requesting job
- Person to whom the photographer should report; also the date and time the services are required
- Description of the job to be photographed
- Uniform the photographer should be wearing

The most important information of the job order is the concise description of the job to be photographed. All information pertaining to the job should be described as clearly and completely as possible to avoid any confusion for the photographer.

Your relationship with the imaging facility personnel should include an understanding that your job orders always allow for a creative or imaginative shot along with the requested standard or sure-shot. In cases where the photographer's shot is better than the shot requested, use the better shot. **Never** request "one to 10 of every shot." Should you be allowed to select

your prints by screening proof sheets or negatives, select only the best shots to satisfy your requirements.

Another method you should use to foster good relations with the imaging facility is to rely on the judgment of an experienced photographer and request the "best view of ..." when ordering prints.

CHAPTER 12

BASIC PHOTOJOURNALISM

Photojournalism is a form of communication that plays a vital part in modern news reporting. To convey their message, photojournalists use a harmonious combination of photographs and words. Many of the leading magazines and newspapers attribute their success to photojournalism. The reason for this is simple—a good photograph can, at a glance, portray the essence of a news or feature story.

Well-composed, action-packed photographs with carefully worded photo captions have reader appeal, realism and permanence. Do you remember the photographs of the raising of the American flag over Mount Suribachi, the signing of Japan's surrender aboard the battleship USS *Missouri* (BB 63), the swearing-in of Lyndon B. Johnson aboard Air Force

One, or Neil Armstrong and Edwin “Buzz” Aldrin planting Old Glory on the moon, or the terrorist attacks that brought down the World Trade Center (fig 12-1). How many of the words written about these events do you remember?

The photojournalist's objective is to communicate primarily through photographs. To be an effective photojournalist, you must understand the following fundamentals:

- **Know your subject.** You cannot communicate information about a subject of which you have no knowledge.
- **Know why you are communicating.** You should always have a purpose for your message.

Figure 12-1.—"Ground Zero" at the site of the World Trade Center terrorist attack, September 11, 2001.

(Photo by PHC Eric J. Tilford)

The purpose might be as simple as sharing an emotion or an experience.

- **Know to whom you are communicating.** Is it a specific audience that has some knowledge of your subject, or is it a “mixed bag”?
- **Know how to use the camera.** Your camera is a mechanical device that only sees a limited area and exercises no selection over the action that takes place in front of it. As a photojournalist, you can use this limited view to exclude extraneous subject matter and to focus on your message. You do this by determining which lens, camera angle, lighting method and timing will capture the photograph that will best communicate your story.

This chapter introduces you to photojournalism and covers some of the techniques by which it is applied. Maximum emphasis is placed on achieving good photographic composition, interest, impact and technical quality. Granted, the basic information contained here is not sufficient to qualify you as a Navy photojournalist in the strictest sense. However, if you learn and use this material, you can become a proficient news photographer and an asset to the public information efforts of your command.

HISTORY OF MILITARY PHOTOJOURNALISM

LEARNING OBJECTIVE: *Recall the history of military photojournalism.*

The history and growth of military photojournalism has been brief, but significant. It started when Matthew Brady and his assistants were commissioned to document the Civil War pictorially. Their photographs were made on wet plates that had to be processed immediately, thus limiting mobility. The film they used was of low sensitivity; therefore, action photography was out of the question. Further, there was no means to get the photographs to the publisher quickly, so interest was limited. No processes for reproducing a photograph in a newspaper were known at that time, except by having an artist copy them into line drawings. These problems did not destroy the desire for photographs or the value of photojournalism as it existed then, but rather posed challenges to cause people to search for a better way to use the photographs taken.

By the time of the Spanish-American War (and the equally important Hearst-Pulitzer circulation war),

camera equipment had evolved into a smaller, portable form. Film on an unbreakable cellulose base had been invented that could be exposed in one place and processed many miles away and many hours later. Film sensitivity had improved so that action could be photographed. Quicker transportation meant more timely delivery of news photographs to the publisher, while their news value was still high. Methods of photoengraving, though still crude, allowed newspapers to print several halftones along with etchings and linecuts.

Military photographers took many photographs during World War I, but the importance of these photographs as an adjunct to the written history of the war was not realized for many years.

The period between the World Wars was very important to photojournalism. “Plaything” photography yielded to more exacting photography as a science. Cameras designed for presswork became available in a price range within the budget of the average newspaper. The sound motion picture, the miniature camera, the fast lens, the flash lamp, flash synchronization, and hundreds of film, emulsion and laboratory innovations were put to use. Most important, the public desired news photographs and editors accepted photography as a tool of journalism.

World War II saw news photography in the military services rise considerably. Early in the war, the services drafted professional photographers and formed teams to document the history of United States international involvement. They went one step further by using their talents to show the horrors of war. They took photographs with stopping power, photographs that had impact and photographs that forced the viewer to look and read the copy.

By the time of the Korean War, photography rose above an improved and exacting science and became a finer skill. Photographers began to document moods and feelings, to look for photographs that expressed what was not readily apparent on the surface and to concentrate on photographs for news releases. It was during this period that the military photojournalist became a professional.

During the Vietnam War years, photography continued its advances in equipment and processes. Along with these advances, photojournalism reached new heights, providing just short of a “you were there” atmosphere of the war. Today, the military photojournalist is a mainstay of the military

establishment—a vital contributor to the internal and external public affairs efforts of a command.

Thanks to modern technology and digital photography, photos that are shot in the field of important events can now be instantly processed and transmitted via electronic means. While there still are major news networks that take their photos with regular cameras, the shift toward digital cameras and digital photography has been swift throughout the industry.

Covering major evolutions in the future may not be as difficult as it was in the past because of these incredible technological advances, but the basic principles of good photography will always remain intact.

PHOTOGRAPHIC COVERAGE ELEMENTS

LEARNING OBJECTIVE: *Identify the elements of photographic coverage.*

Photographic coverage is invaluable in most publications. Through effective layout, photographs can be used independently as lead stories with merely a cutline accompanying them. In other uses, photographs can support headlines and written spot news accounts as well as feature stories.

The photograph serves as a definition for words. No two people imagine identical photographs through words alone. Groups of words rarely cause similar mental images in everyone. Different people see different photographs in their mental interpretations of verbal descriptions of a given scene. From a photograph, everyone gets the same mental picture.

TYPES OF NEWS PHOTOGRAPHS

What is a news photograph? Just about everything said about recognizing and gathering news also can be applied to the news photograph. News photographs also have common news elements. These same 10 elements—immediacy, proximity, consequence, prominence, suspense, oddity, conflict, sex, emotion and progress—are essential to successful photojournalism. You can judge the newsworthiness of a photograph by the degree to which these elements are present. The newsworthiness of a photograph, like that of an event, depends on the strength of intensity of the news element it contains.

Nearly all news photography is classified into two categories: **spot** and **feature news**. This applies to

sports as well as any other type of newsworthy activity. Since the spot news photograph achieves a dramatic quality, the unrehearsed action is obvious to the reader. The feature photograph, on the other hand, consists of elements that allow it to tell its story with a brief cutline, or on many occasions, without a cutline.

Spot News

In covering unrehearsed action, control over the kind of photograph you will get is somewhat limited by the situation. For example, in shooting a boxing match, you work at top speed and usually under great pressure. You record developments as they occur with little regard for the control of the men in the ring. Your ingenuity and alert observations will have to be called upon to ensure any technical quality at all. In shooting well-known personalities, you should photograph them doing something. A photograph without action, regardless of the prominence of the personality, is not in itself a storytelling photograph. The successful and usable news photograph has action and impact (fig. 12-2) and immediately draws the reader's attention either to the cutline or to the accompanying story.

Feature News

The purpose of the photo feature is to tell a story about a given subject, selected and planned by the photojournalist, using real people or real things, in real or believable settings. As the photojournalist, you arrange everything to appear as if the story is actually happening; you will have full control over composition, posing, arrangement and expressions of the subject. An example of an award winning feature photograph is shown in figure 12-3. You should create a lighting effect that establishes mood or realism in your photograph, and select the precise camera angle needed to give emphasis to your photographs.

In shooting the feature story, you are rarely hurried and there are opportunities to change your setups if you are not entirely satisfied. You also may take time to exercise your technical know-how (in processing control) to produce a photograph of the highest quality. An additional advantage of feature photography is that you may “cover” yourself by taking additional photographs; the straight news photographer is afforded little more than a split second for the quick “grab” shot.

Figure 12-2.—Award-winning news photograph with action and impact.
(Photo by PH3 Brian Fleske)

Figure 12-3.—Award-winning feature photograph.
(Photo by JOC Robert Benson)

COVERAGE PLANNING

Planning is essential to good news photography. When you are aware of the subject or event you want to portray, plan the photographic coverage so the story may be told through photographs alone, if necessary. The photographs must have imagination and a professional news touch if the results are to be acceptable to the news media.

Strive for simplicity, interjecting the human element into your photographs. Create impressions, use people and always remember that it is people and what they do in everyday life that make news.

Keep the following tips in mind when you plan coverage of news events:

- Shoot only when you have in mind the type of photograph you intend to take.
- Keep the photographs from looking posed. Posed photographs are permissible and for best results, it is often necessary for subjects to pose, but this fact should not be discernible in the finished photograph (fig. 12-4).
- Set the stage, place the props for dramatic effect and tell the people what to do and how to look. As we emphasized in chapter 11, you must be in charge when directing photographic subjects.
- Resist the temptation to ask the photographic subject(s) to “hold for one more.” Most people will do almost anything required for the first take; thereafter, they lose interest quickly in cooperating with the project, and the photograph ultimately suffers. However, if you feel that for some technical reason you did not get the photograph the first time, do not hesitate to speak up and ask for another shot. Remember, you were sent on the assignment to get pictures, and this is what you are expected to deliver.
- Photograph the faces that fit the emotion. A smile or pleasant expression does not show a lack of dignity; it shows that Navy men and women also have fun.
- Move in on your subject and make your photographs show the desired action. Seldom, if ever, will you be concerned with sweeping panoramas, unless they tell the story you want told.

Figure 12-4.—“Posed” photographs should appear as if the action is spontaneous.

(Photo by PH2 James Watson)

- Learn as much as you can of the event, the shooting locale and the principles involved before you leave the public affairs office.

Identification

Always record sufficient information so you may properly identify and prepare cutlines for your photographs upon returning to your office. Using a notebook or caption log to record cutline information was covered in chapter 9. Additionally, you may have an assistant jot down the information or tape record it as you go along.

Shooting Script

Some professional photojournalists plan their shooting with great care, including a complete shooting schedule or script. You should study the script before the assignment and commit it to memory, rather than checking it shot by shot at the scene. Often, you may have to depart from your script when shooting at the scene. You must stay one jump ahead of the action, and when the unexpected occurs, be prepared to make a change—remembering your story angle and objectives.

A good script is usually divided into two parts. The first part is concerned with the general idea of the picture story. All pertinent information, such as names, places, times and contacts are listed in this part. The second part lists the picture ideas and the information pertinent to each shot.

PART ONE.—The research of a photo feature theme is of the utmost importance to the success of any picture story. A firm idea of what is going to be shot and the approach that will be taken is needed before shooting can begin. Therefore, in part one of the

shooting script, you should complete the following sections:

Who—The name of the individual or subject that will be photographed. The job, title and duty responsibilities of the subject should be included, if applicable.

What—The exact nature of what the subject will be doing in support of the overall theme of the photo feature.

When—The time and date the subject will be photographed. Make sure the subject will be available at the time specified.

Where—The exact location or locations where the photography will take place. Make sure the specific area will be available at the time indicated.

Why—Why will this photo feature visually interest your audience? State the reason(s) why the subject will appeal to a given audience. (**Preplanning**—List three to seven picture ideas in order of their visual flow.)

How—List all arrangements that must be made to enable you to carry out the assignment. Include name(s) and telephone number(s) of contact(s) assisting with the event. Also list the photographic equipment (type of camera, lenses and specific lighting accessories) and props you will need.

PART TWO.—Part two of the shooting script should contain a well-planned list and description of, and reasons for, the photographs you determined will best represent the story. For example, if you were doing a picture story on the Navy's flight demonstration team, the Blue Angels, one desired photograph might be identified as follows:

SHOT 1: LONG SHOT

INSTRUCTIONS: Aircraft flying in close formation. Shoot with the operations tower in the foreground, from low angle, for perspective.

REASON: To show the reader the precision flying ability of the "Blues" and to identify the location of their performance.

Other planned photographs in the photo feature should be addressed similarly. The following information should be listed for each proposed shot:

- The angle of view (high, low, front, side, back and etc.)

- The action (implied or actual) expected to take place
- The type of shot (long, medium, close-up or extreme close-up)
- The desired depth of field or point of focus
- Any unusual lighting conditions

Finally, you should storyboard each picture idea to assure a unified picture page with emphasis placed on leading lines, lines of force, framing or rule of thirds. Storyboarding (fig. 12-5) entails sketching out each planned photograph beforehand, giving visual direction to your list of desired shots and numbering the sketches accordingly.

The sketches do not have to be works of art (stick men representing your subjects will suffice), but they should be recognizable as visual descriptions of the planned photographs on your list.

Remember, the shooting script is only a guide for shooting a picture story. With a basic idea of the subject and its importance (accomplished through research), you can better understand the subject and obtain superior results.

Shooting Script Techniques

A good shooting script should include the following techniques:

- **Change of pace.** During the actual shooting session in covering a particular subject, interest must somehow be maintained in the story. Interest can be retained by having a change of pace or variety in the coverage technique used by the photographer. Static coverage of a subject can be eliminated by first understanding the reason for certain types of pictures to be taken, and second, by keeping these points in mind during the script writing and the actual shooting.
- **Long (perspective) shots.** Taken from a distance or with the aid of a wide-angle lens, long shots show the subject in its entirety, relate it to its surroundings and clarify the relationship of its different components to one another. They are photographs that, at one glance, present many different aspects of a subject that subsequently is further explained in some of the other photographs in the story. This type of photograph is best taken from a high vantagepoint, such as a roof, scaffold or ladder.

Figure 12-5.—Storyboard.

- **Medium shots.** Medium shots normally comprise the bulk of the photographs that make up the picture story. They correspond to the impression the eye receives in reality. They are used to show people, objects, things, interiors and action.
- **Close-ups.** Close-ups are explanatory photographs that permit the photographer to show important aspects of the subject in greater clarity and detail than would have appeared in reality to an observer. Only in the form of a close-up can a face, pair of hands performing a

certain function or small but important object appear monumental, interesting and in proper proportion to its significance to the story.

- **Horizontal and vertical views.** Shoot both horizontal and vertical views of your subject—with the same action portrayed when possible. This provides more latitude when you construct a picture story layout. You can usually crop long shots during the layout process to meet design requirements, but not medium and closeup shots.

Tentative and Final Layout

Picture stories are not just a haphazard gathering of photographs. The photographs used must have specific functions. The use of one photograph, as opposed to another, is closely aligned with the layout design. Even as you take photographs, you should consider the picture story layout.

The lead photograph is not necessarily the first picture in chronological sequence, but the picture that contains the essence of the story. Within the layout, the lead photograph is usually the largest and placed to attract the reader's attention.

Body photographs are those that actually communicate the story. They must use compositional techniques to present interesting and stimulating photographs. The editors should strive to present the photographs in different sizes and formats as well as presenting rights and lefts, highs and lows, longs and close-ups and at the same time, using the minimum number of display elements. Allow for maximum latitude when selecting your visuals.

You also should consider end photographs during the planning phase of the picture story. Not all picture

stories have definite endings, but all should bring the reader to the significance of the story.

After accomplishing the preceding tasks, you are ready to take photographs. The law of averages indicate that the more you take, the better your chances are of getting exactly what you want. However, if you are properly prepared, your photographs will not be a number of unrelated shots, but will be several sequences that cover the specific picture ideas listed on the script. This method was used during the first landing of the space shuttle. By covering your assignment in this manner, you will have a variety of visuals that can be used in a picture page layout (fig.12-6).

Equipment Readiness

Speed is the essence of news photography, especially spot news that just happens. Therefore, it is crucial that you always have a ready camera on hand with an adequate supply of film, flash and associated equipment. When a spot news event occurs, you will not have much time to get your gear together and check it out. This means you must start your day off with a complete check of the equipment available to you.

When possible, keep two cameras ready—one loaded with black-and-white film and the other with color slide film or a digital camera (for release to electronic media).

As you learned in chapter 11, you should keep your camera free from dirt, dust and moisture and handle it with care. Store it in a readily accessible place in its carrying case when not in use.

Self-Confidence

Gaining an attitude of self-confidence is one of the most difficult and important aspects of becoming a

Figure 12-6.— Picture sequence in a picture page layout.

(Photo by PH2 James Watson)

good news photographer. A “personality for the profession” is a prerequisite for anyone who wants to become proficient in the field of photojournalism.

To succeed, you must look upon occurrences with an objective view. The knowledge of the mechanics of photography is not enough. You must have an inquisitive nature that inherently causes you to want to know more about what is going on around you. Diligence, study, and practice are necessary to use the tools of the trade proficiently; aggressiveness and the willingness to understand the motivations of others will aid you in your quest for competence.

Those who have a thorough knowledge of their field and consistently display such attributes as honor, use finesse, diplomacy, courtesy, and honesty, as well as straightforwardness, automatically develop self-confidence.

All too often a photographer misses pictures of great pictorial value because of the lack of aggressiveness. Upon receipt of an assignment, your whole attitude must be that of determination. Come what may, you must get photographs. Navy Photographers and Journalists are frequently in contact with notable personalities from military organizations, local and federal governments, foreign countries, private industry and hundreds of people from all walks of life who at some time or another have had an association with the Navy or other armed forces.

Almost without exception, all of these people may be photographed without incident under nearly any circumstance. Fear of what is ahead and fear of standing in the shadow of great people cannot be a part of the personality of the news photographer. You should be respectful, as appropriate, but you should never feel subservient or inferior. Finesse, courtesy and straightforwardness in pursuing the job at hand immediately result in cooperation as well as quick action in seeing that the mission is accomplished.

People being photographed rely on the photographer’s ability to get the coverage desired and usually await the photographer’s instructions. Photographers and reporters are not unfamiliar sights to the VIP. When people have reached a point in life when they have become public figures, they are conscious that they no longer enjoy the privacy of the average citizen. Therefore, knowing they are news, they are ready and willing to assist members of the working media. However, they cannot do this until you have presented yourself. When your presence is noted, your VIP subject knows, through many years of

experience, that your job must be done with speed in order to meet deadlines.

In presenting yourself to a subject, the initial introduction normally is made by an aide or assistant; however, there are times when you must do this yourself. An honest and courteous approach at a diplomatic moment can be done easily. Simply remain in close proximity to your subject and await the earliest break in conversation; then step forward and state your name, rate, place of duty and your reason for being there. When you are acknowledged, take the minimum time necessary to get your photographs. Work with sureness, deftness and thoroughness. If you feel you did not get a photograph, bring this to the attention of your subject immediately. Often you will find that straightforwardness gets you a second chance that so seldom comes to the news photographer. If it is impossible to shoot another photograph at that particular moment, keep your eyes open and remain on the alert. Another opportunity may present itself, so be ready for it.

CREATING GOOD PHOTOGRAPHS

LEARNING OBJECTIVE: *Describe the basic elements of creating good photographs and the inherent security and safety considerations.*

Creating good photographs (news, feature or otherwise) depends heavily on the imagination and know-how of the person behind the camera. You must have a storehouse of imaginative ideas for presenting simple, yet interesting photographs that emphasize a definite point of view. The shot must have both visual and emotional impact and offer the viewers a perspective they do not always see (fig. 12-7). All of the qualities mentioned are a must for a news photographer striving for good photographic composition.

Essentially, photographic composition is a harmonious combination of a main subject and its supporting elements. This means you must be able to recognize these elements and then arrange them into the photograph that will tell your story.

Learning the art of good composition is similar to mastering any other skill. First you must understand the rudiments. Then, through much practice and attention, you develop your talent to the highest degree of perfection possible.

In the early stages of learning, we depend almost exclusively on what we can see and hear, imitating

Figure 12-7.—Feature photograph offering a unique view of the 2001 terrorist attack on the World Trade Center in New York City.
(Photo by JO1 Preston Keres)

what has been done before. Much can be learned about composition by studying various works of art and collections of good photographs. Each one offers an example of how to present a subject in an effective and interesting manner. By attempting to duplicate some of these photographs, you can acquire an understanding of the basic elements of composition.

The proper placement of the subject within the space of the photograph is one of the most important elements of good composition. Whenever possible, you should select and arrange the subject elements, choosing the viewpoint and lighting conditions that present the subject best. You also should arrange the subject in the photograph in such a way as to clearly and predominantly be the main point of interest. The main idea of the photograph should be recognizable immediately to anyone viewing your photograph.

In aiming for good composition, you should learn and use the following principles as guides:

- Simplicity
- Point of interest
- Compositional lines
- Balance
- Forms
- Rhythm or pattern
- Tone
- Depth perception
- Action
- Security and safety considerations

Your awareness, application and practice of these principles when composing a scene will assist you greatly in making an interesting presentation of your subject.

SIMPLICITY

Frequently, the simplest arrangement of your subject matter makes the most interesting presentation. Although each photograph consists of numerous small parts and contributing elements, none of these should appear conspicuous or portray more interest than the main object. The main object is the reason for making the photograph in the first place; all other elements should merely support and emphasize it. The scene should not be cluttered with a confusing number of objects and lines that detract from the subject. You should select a viewpoint that eliminates surrounding

distractions, making the principal subject readily recognized. If numerous lines or shapes are competing for interest with the subject, it may be difficult to recognize the main object or determine why the photograph was made.

Study the scene from all angles and decide exactly what you want to show; then strive to maintain this single idea as clearly as possible by eliminating unimportant or distracting elements from the photograph. Keeping the arrangement simple makes the job of composition easier and the photograph more interesting.

POINT OF INTEREST

With few exceptions, most photographs should have a single point of interest that tells the viewer this is the reason for taking the photograph. All other details support the point of interest. The point of interest is the point to which the eyes are drawn (fig. 12-8). If there is nothing in the photograph to attract attention to a particular area, the eyes wander throughout the scene. The point of interest may be a single object or numerous ones arranged so that attention is directed to one definite point.

Lines, shapes, human figures and so forth, should be directed so that they look or move toward the point of interest in the picture. If you have a group of people gathered around a table, keep the interest intact and centralized by having them look at each other or at one individual of the group. A perfect example of this is *The Last Supper* by Leonardo da Vinci. This unit of interest causes the observer's eyes to be drawn to the same point. Human figures attract attention more strongly than most other subject matter.

Figure 12-8.—The eyes of the viewer are drawn to the point of interest.

For instance, a photograph showing a person standing at a distance in front of a building may leave the observer wondering whether the person or the building is the main subject. When you include people in a scene, do not photograph them looking directly at the camera. When people look directly at us, we normally return the gaze by looking directly into their eyes. However, when they look in another direction, our attention is drawn from them to the point at which they are looking. Thus if people are grouped around a piece of machinery or an aircraft (the main object of the photograph), have them look at the object, rather than at the camera.

Rule of Thirds

Point of interest, as used in this section, is frequently called the center of interest. It is called “point” at this time simply to prevent giving the impression that it would be located in the center of the photograph space.

Although good composition can at times be obtained by placing the point of interest in the geometrical center of the photograph area, it is a good idea to avoid placing it there. Too frequently it divides the photograph into equal halves and makes it difficult to create a feeling of balance. Some photographers draw lines on the ground glass, dividing the photograph into thirds both vertically and horizontally, and thereby locate the point of interest at one of the four intersections of these lines. This division is sometimes referred to as the rule of thirds (fig. 12-9)—a concept briefly covered in chapter 8. You will find that one of these intersections is the best location for the point of interest and gives the best feeling of balance to the composition of the photograph. Most of the attention should be attracted to and held at this point. An artistic feeling for arrangement is an invaluable aid in composing a scene in order to make a striking photograph.

If the principal object is too close to one edge, appears top-heavy, or if it in any way leaves the observer feeling that it is misplaced in the photograph, the point of interest should be moved to another location. You also may change the camera angle to include another object and balance the composition.

Leading Lines

One of the most common techniques in directing attention toward the point of interest is the use of leading lines, shapes or patterns. You can use leading lines to convey psychological impressions; curved

Figure 12-9.—The rule of thirds.

lines lend grace to a photograph and strong horizontal lines combined with vertical lines indicate strength and power. The leading line may be a road, an arm or leg, a shoreline, a patch of light or dark tones in the scene or a line of sight or the mooring lines of a ship (fig. 12-10). A good leading line is one that starts near a corner of the scene and continues unbroken until it reaches the point of interest. It should end at this point; otherwise, attention is carried beyond the main object in the photograph.

Foreground and Background

The area in front of and behind a subject can be used to develop depth in a photograph. For example, when you place objects relevant to the subject in the foreground, the foreground and the subject (in the middle ground) both become elements of interest in the photograph.

However, you should avoid a busy foreground or background. Too many details or unattractive components will detract from the main subject. For instance, a flag pole or a sword in the command insignia appearing to grow out of someone's head obviously harms the effect of the photograph.

The foreground or background also can be blurred intentionally by camera settings and selective focusing to draw attention to the subject.

Figure 12-10.—An example of good leading lines continuing to the point of interest .
(US Navy Photo)

Framing

Another method of confining attention to the point of interest is by framing it with foreground objects (fig. 12-11). The object could be an arch, a window, a tree limb or even an arm or leg.

Camera Angle

The camera angle also is very important in good composition. It can help you place emphasis where you want it. Angles can be used to create the unusual when the scene is commonplace. Using a high, low, left or right angle relative to your subject can produce an entirely new effect. Avoid shooting everything from the common eye level. This is the same view seen by your viewer all day long. Walk around the subject and determine which viewpoint will have the most impact or the most pleasing effect.

When the camera is placed above the level of the subject, it creates a distant and detached view. Shooting from a low angle produces a dramatic and a statuesque effect (fig. 12-12). When the camera is aimed at a 45-degree angle toward the subject, it lends depth to the subject and gives the best identification. On the other hand, a frontal view creates a flat appearance and will not last very long in the viewer's mind.

(Photo by JOC Robert Benson)

Figure 12-12.—Award winning black-and-white action photograph shot from a low angle.
(Photo by PH3 Saul Ingle)

Lighting

Lighting is one of the important creative elements of composition. When you control the light and direct it where it is wanted, minor objects or distracting elements in the scene can be subdued and thereby give more prominence to the main point of interest. The type of lighting best suited for a subject depends on the type of subject and the purpose of the photograph. If maximum detail is desired in the shadows, the illumination should be soft and diffused. Sidelighting is most effective in showing texture. However, light falling diagonally on the subject from above and to one side of the camera is the most natural form of illumination. We are accustomed to seeing most subjects under this condition in which the shadows are cast off to one side and slanted away from us, creating the greatest apparent depth and roundness in the subject.

Shadows are the key to apparent depth in a photograph. Without shadows the subject is without form, curvature or texture, appearing flat and lifeless. This does not mean that shadows should be harsh and black to achieve these effects. They may be soft, yet of sufficient density to show the most delicate roundness of form. As a general rule, harsh black shadows are undesirable in a photograph due to the complete loss of

detail in them. From a compositional standpoint however, black shadows can be very useful in balancing a scene and directing attention to the point of interest.

While viewing the scene from various angles to select the best camera position, note the effects of illumination. In all probability, the most complimentary lighting on an outdoor subject occurs only during one short period of the day. For this reason, time your photograph to take advantage of the most suitable available light or plan to create your own illumination with auxiliary lights.

Silhouetting

Silhouetting is when a subject is backlit and then underexposed. A silhouetted subject gives overall strength to a composition and isolates the subject through contrast of the dark foreground against the lighter background (fig. 12-13).

COMPOSITIONAL LINES

The formation of lines in a composition is unavoidable. For example, lines are formed by the horizon, a person's limbs, the side of a ship, a fence or a winding road. These lines—vertical, horizontal, diagonal or curved—lend their own element of emphasis to a composition.

Vertical lines formed by elements in composition suggest strength and dignity (a sentry at attention), while horizontal lines suggest tranquility and rest (a ship on the horizon at sunset). The diagonal line suggests action (climbing aircraft) and a variety of lines indicates activity. A feeling of grace and beauty is conveyed to the viewer by the use of curvaceous lines, such as those used in glamour and fashion photography.

BALANCE

A good composition should have balance. In other words, your viewer should not get the uneasy feeling that the elements may come tumbling out of your composition.

A balanced composition gives a feeling of harmony to the whole setting. Elements of balance are placed in opposing sections of a photograph in such a manner that each section appears to have an equal amount of weight or value, and the objects all appear to belong in the scene. Balance can best be achieved by

Figure 12-13.—Award winning photograph featuring a silhouetted subject.

(Photo by JO1 Preston Keres)

offsetting unequal sizes, shapes, tones or objects in a scene.

A good method of balancing objects of unlike shapes and weight is by placing them at unequal distances from the imaginary center of support. In other words, a small object placed a greater distance from the center counterbalances a much larger object just as though they were on a pair of scales. A small object of considerable importance and weight can be used to balance effectively a large but less important object (fig. 12-14).

The mental impression of weight is a factor in determining the relative placement of objects in a scene. Size alone does not determine the weight or value of an object. The tone of the object and

Figure 12-14.—Compositional balance is used to bring the smallest object in the photograph, a camera, into focus.

(Photo by PH1 Franklin Call)

placement in the photograph are factors in determining its importance.

FORMS

In analyzing masterpieces to learn the secret of their effectiveness, some experts found that the parts of the photograph are grouped according to some geometrical form. This finding can prove useful in planning the composition of your photograph; however, you are cautioned against applying it too mechanically. If you use these forms without modification, the resulting photographs are likely to be stilted and dull. The real trick is to use them in such a manner as to hide them partially.

The most important basic forms are as follows: the pyramid (sometimes called the triangle), the circle, the cross, the “L,” the radii and the “S.” All of these forms may be used in composition of material in a vertical plane or in a photograph involving perspective. Combinations of these forms, such as a circle and a cross, may appear in one photograph.

Pyramid

The pyramid form (fig. 12-15) suggests symmetry, solidity, aspiration or dignity. We see it in religious photographs, in church spires and in portraits with the head as the apex of the triangle.

Circle

The circle lends itself to flower studies, still life, graceful groups or landscapes framed in trees.

Cross

The cross composition is found in a sailboat with its reflection in water forming one line and the horizon forming the other.

“L”

The “L” composition may occur when a tree at one side of the photograph forms an “L” with the horizon line.

Radii

The radii composition has lines leading into a center, or out from it, as spokes lead to the hub of a wheel.

“S”

The “S” composition, covered earlier as curved lines, is undoubtedly the one photographers use most and the one most popular with viewers (fig. 12-16).

RHYTHM OR PATTERN

One word often heard in connection with photographs is rhythm. It simply means a repetition of some kind and may be a shape or a line (fig. 12-17). An illustration in nature is that of a field of wheat, blown by the wind, with each shaft of grain being uniformly bent in the breeze, producing rhythm with changing patterns.

TONE

Tone refers to the color of each object in a photograph. In black-and-white photography, the gray would run from white through all shades of gray to black. One of the most effective ways of giving impact to the point of interest is to contrast it sharply by color with the other objects in the photograph.

Variations in tones or contrast are important elements in the distribution of weight in a composition. Darker tones create the impression of greater weight. Thus a large light-toned object can be counterbalanced by a smaller dark-toned object. The contrasting tones may be nothing more than shadows or cloud formations. The balancing of equal or unequal tonal areas can be simplified by dividing the photograph space and arranging the objects in opposite thirds of the photograph or at the intersections of the vertical and horizontal lines.

DEPTH PERCEPTION

As far as the physical characteristics of a photograph are concerned, it has only two dimensions—length and width. Nevertheless, since we are accustomed to viewing nature in three dimensions, it is important that photographs also give the illusion of depth to make them appear more realistic.

The impressions of depth and distance are normally obtained when you mentally compare the relative size of various objects—near objects appearing large and the more distant objects much smaller, even though they are the same physical dimensions. You can easily create the illusion of depth in a photograph by placing common objects in the

Figure 12-15.—Pyramid form of a destroyed building.
(Photo by PHC Eric J. Tilford)

foreground or background, so the relative sizes of all objects can be determined.

You can also create depth by selecting a camera viewpoint that gives the impression of distance by perspective. This illusion of distance is sometimes

enhanced when you exaggerate the perspective by changing the camera position, by using a wide angle lens or by emphasizing texture and modeling through the use of strong sidelighting. Focusing the principal object critically sharp and leaving the background

Figure 12-16.—"S" composition used to balance the small boat and the Navy ship in the photograph.
(U.S. Navy photo)

Figure 12-17.—An award winning feature photograph using rhythm composition shows an Electrician's Mate 2 Class at work aboard USS Blue Ridge (LCC-19).

(Photo by PHAN Kurt Fischen)

somewhat out of focus usually directs more attention to the subject and tends to increase the feeling of depth. Backlighting the subject gives better separation and makes it appear to stand out more prominently from the background, accentuating the subject and increasing the feeling of depth.

The feeling of depth also can be increased by making the foreground darker in tone than the main point of interest or the background. In some cases, this is done during printing by simply burning in the foreground.

ACTION

Action in a photographic composition can be either physical or implied.

In physical action, such as a fleet runner, the motion or position of the runner cannot be held. It changes after the split second in which the photograph is taken.

Action can be implied by a position that suggests a physical action will take place, or it can be facial in which the subject's face suggests or expresses action or a definite emotion.

Good action is shot at its peak, as shown in figure 12-18. Where the action is fast moving, as it is in a sporting event, the peak of action is short and sometimes difficult to determine. To capture this action requires precise timing and know-how. However, in feature development you have the

Figure 12-18.—Award winning action photo shot at its peak.
(Photo by PH3 Saul Ingle)

advantage of being able to plan the action logically after studying the job.

SECURITY AND SAFETY CONSIDERATIONS

Because of the many new technical developments in the Navy, you will probably come in contact with security problems early in your job as a news photographer.

Photographs disclosing pertinent detailed information of a classified nature are to be accorded the same classification as the subject of the photograph. No classified photographs can be released for publication or transmitted by electronic means.

Officers in command status are responsible for taking official or unofficial photographs and for the supervision, censorship and release of photographs. Unofficial photographs taken aboard ship, station or aircraft are either submitted to the CO or a properly designated officer (such as the PAO) for screening to assure that no classified matter is revealed.

The review of photographs must be objective in nature. The prompt release for publication of unclassified photographs of interest to the public and beneficial to the Navy is considered mandatory. Photographs of general naval life, such as ceremonies and athletic events, are not considered to be of a classified nature and should be released automatically. Photographs of doubtful classification for which release is desired must be referred to CHINFO.

Another violation you should be aware of is that of safety. An example is photographing a Sailor aboard ship using an electric deck grinder without safety goggles or wearing unauthorized rubber gloves. If you

are not sure of the correct safety measures for a given task, ask the command safety officer.

THE PICTURE STORY

LEARNING OBJECTIVE: *Identify the different types of picture stories and the applicable technical requirements.*

Knowing the detailed techniques for developing a picture story are requirements for senior journalists. However, at the JO3 and JO2 levels, you should be familiar with the various categories of picture stories.

TYPES OF PICTURE STORIES

There are seven basic types of picture stories and they are classified as follows:

- Illustrated text
- Photo-text combination
- Pure picture story
- Picture story within text
- Single picture story
- Abstract picture
- Informal portrait

Illustrated Text

For this type of picture story, the text or story is written first, then one or more photographs are used to illustrate, or dramatize, its content. In reality, this is not a true picture story, since the photographs are incidental, rather than an integral part of the text. The photographs are used to dress up the page, make it attractive, give it character or establish a mood. Many magazines use the illustrated text format. They frequently introduce each story with a single illustration, full-page size, which serves to attract the readers' attention and leads them into reading the story.

Photo-Text Combination

As the name indicates, the photo-text combination type of picture story uses a combination of both photographs and text. However, the photographs carry the weight of the story. The story is told primarily by related photographs arranged in some form of continuity. The text is important and provides worthwhile information relative to the photographs, but it is subordinate to the photographs. This is the

easiest type of photograph story to develop and the one most commonly used in the Navy.

Pure Picture Story

In the pure picture story there is no text except for a brief introduction outline. Of the seven picture story types, the pure picture story is the most difficult to develop. It is frequently presented in sequences of photographs taken at brief intervals. For example, a pure picture story of a VIP's arrival might show the aircraft landing, the disembarkation from the aircraft, handshaking with the greeting party, the inspection of an honor guard and the VIP entering a limousine. Pure picture stories normally are used only when the action is simple and familiar enough to the average reader so that no lengthy word description is required.

Picture Story Within Text

The picture story within text actually presents two separate but related stories. One story is told in words, the other in photographs. Both are complete in themselves. The text may be used without the picture story, or the picture story may be used without the text. Nevertheless, the combination of the two in a single layout makes the spread much more effective than either would be alone.

Single Picture Story

The single picture story is the most basic form of photojournalism. Single photographs, filled with impact, allow the viewer to “feel” the action and thus become involved with the subject.

The single picture story is similar to the lead photograph used in a longer picture story. It sums up the subject, evokes some emotion, or keys the action or the setting. The single picture, while strong, is also simple.

Every photographic situation is different so there is no magic formula to tell you how to put impact or strength into a photograph to make it meaningful. Occasionally, the single meaningful picture is simply a matter of luck—being at the right place at the right time. More often, the photograph is the result of careful planning. In either case, the event is only captured because of the photographer's timing (fig. 12-19). “Timing” means capturing the moment of greatest significance. There is no exact way of predicting that moment. To be successful, you must anticipate what is coming and be ready when it arrives.

Figure 12-19.—Award winning feature photograph used in a single picture story.

(TSgt. Greg Kobashigawa, USAF)

Abstract Picture

You may be objective or subjective in your approach to a subject. This is considered an abstract picture approach. When you use the objective approach, try to record the subject as faithfully as possible, presenting the subject for the viewer's own interpretation. When your approach is subjective, you engage your own feelings in your work. You approach the subject from the standpoint of your reactions. You want the viewer to feel as you felt when you recorded the subject. With this approach, the viewer is handed the reactions of the photographer and sees the subject as the photographer saw it.

It is the subjective approach that must be used to photograph the abstract—thoughts, emotions and so forth. These are the subjects that primarily involve feelings rather than facts.

A photograph that captures an abstract idea or emotion conveys to viewers something with which they can identify. It stimulates their imagination and causes them to react emotionally.

To sense and capture abstract elements, you must have an understanding of what makes people react. Additionally, you must react yourself. You must see beauty and ugliness, feel love or hate, wonder at the great and small and sense and appreciate your own emotions (fig. 12-20).

**Figure 12-20.—Abstract photograph of World Trade Center damage at “Ground Zero,” September 2001.
(Photo by PH2 James Watson)**

To communicate the abstract in photographs, you must develop and use your inner sensitivity. The more it is used, the more your photographs are to be a successful reflection of your experiences and emotional nature. Plus, the more these elements appear in your work, the more viewers become involved with the photographs.

Informal Portrait

Strong, expressive informal portraits are the result of a successful interaction between the photojournalist and the subject.

The most important element when shooting an informal portrait is for you to convey the character and personality of the subject honestly.

With few exceptions, the informal portrait shot cannot be in a studio where the subject is posing. In this situation the subject may appear very formal and withdrawn.

The informal portrait is best made when the subject is candid. This means photographing the subject in familiar surroundings, such as his home or place of work. In these surroundings the subject's hands, gestures and facial expressions begin to convey character and personality.

The informal portrait is an excellent medium for relieving the boredom of the plastic formal portraits, the police mug shots and the "grip and grins" in Navy newspapers. If a person is of the caliber or character to be selected "Sailor of the Year," project that character and personality rather than the person's ability to shake hands.

Do not expect to get the best possible informal portraits by taking only two or three photographs. When you start, your subject will very likely be uneasy and tense. However, as you shoot, the subject will usually begin to relax.

The eyes (which must be in sharp focus) and the mouth are the important parts of the informal portrait. They are where the expressions, unique to each person, are revealed. Your job is to coax the expressions out of the subject. Usually, you can do this through a little conversation while you are shooting or by having the subject engaged in work or talking with another person. When the subject becomes involved and forgets the camera, the real expressions begin appearing (fig. 12-21).

There is no strong rule on how much of your subject should be included in your portrait. Ideally, an informal portrait will include everything that relates to the subject and nothing that does not. In some cases, this will mean including parts of the background because it relates to the subject. Or, it will mean throwing everything out of focus except the subject's face. A general rule is to keep the portrait simple and concentrate on the face.

Quite often it will be the available light that is the determining factor for adding depth and mood to the subject. Although formal portrait lighting should be avoided, you should master its techniques. This will give you an understanding of the various effects of lighting and the changes they can make to the mood or shape of a subject's face.

The best lenses to use for informal portraits are medium telephotos between 85mm and 105mm. A medium telephoto will minimize the distortion you may get by working too closely with a normal lens, and it will allow you to work at a distance from your subjects that may make them less conscious of the camera.

TECHNICAL REQUIREMENTS

Always keep in mind that the only reason for you to take a news photograph is to get it published. A print suitable for personal viewing may be wholly unsuitable for reproduction in a newspaper or magazine.

Most print media use the halftone reproduction process in which photographs are converted into a pattern of dots. These dots vary in size according to the intensity of the tone they will produce. In light areas, the dots are so small they are almost invisible. In dark areas, the dots are so close together they look like a

Figure 12-21.—An award winning informal portrait captures the emotion of damage control training evaluators between classes.

(Photo by PH1 Dolores L. Anglin)

solid mass of black. The amount of printing ink applied by the dots, of course, is in proportion to the light and shaded areas of the original print.

Because of this factor, photographs intended for reproduction must be clean and bright. The black must be strong enough to withstand a little “watering down.” Important halftones in the photograph must be separated clearly, so they will not blend in with each other or become lost altogether in reproduction.

Therefore, a photograph can be good in content and composition, but not usable for reproduction because it is lacking in the following three required technical elements: focus, detail and contrast.

Focus

“Focus,” as covered in chapter 11, means that the subject must be distinct and the image sharply defined. Focus for reproduction must entail extreme sharpness since halftones lose some of their original sharpness in the reproduction process.

Detail

The halftone will not produce fine detail. Small detail in a newspaper is usually lost; therefore, detail must be overemphasized. The most effective way to emphasize detail is to move in close with the camera and concentrate on small areas. Any detail that is important to a photograph should be as large as possible and adequately lighted by natural light or the addition of fill-in reflectors or flash.

Contrast

Contrast is the difference between the light, dark and the intermediate tones of a photograph. A photograph with normal contrast will have an image with a full range of tones from white to black with all the intermediate grays. The image will be boldly defined but will not reproduce well. A photograph low in contrast or “flat” has many intermediate gray tones but lacks clear blacks and whites. It has no brilliance or snap, lacks strength and appears dull. It will reproduce in halftones as an indistinct or “muddy” blur. Only a photograph of normal contrast can be considered usable for halftone reproduction.

SPORTS PHOTOGRAPHY

LEARNING OBJECTIVE: *Identify the techniques used to take sports photographs and record outline information.*

Sports photojournalists must know the sport they cover inside and out and demonstrate a keen ability to spotlight the key plays and players. While luck helps, more often, anticipation and a good working knowledge of the event are the foundation of a good sports photograph. Sports photography captures action; therefore, you must research the sport before game time to understand some of that action and to be prepared for it.

RESEARCHING THE SPORT

If you have never photographed a particular sport, prepare yourself by conducting research. Go to the library and read up on the sport, and if possible, watch a game or two (either on television or one played by local teams). Understanding basic strategies, rules and plays will help you capture the important moments of the game.

COVERAGE PLANNING

When you plan photographic coverage of sporting events, you should keep in mind the two main areas, action and people.

Action

Physical activity is the key ingredient of a sports photograph. Your photograph should not be static—sports action **must** take place. For instance, in football, the running back might break a tackle, the quarterback release a long pass and the linebacker make a sensational, back-breaking tackle. In basketball, the power forward might take the ball to the rim, the center slam-dunk his points home and the shooting guard drain a three-pointer. In softball/baseball, the extra hitter (fig. 12-22) (designated hitter) could send an 0-2 pitch over the fence, the base runner tag up at second and go to third or the shortstop make a sensational diving stop in the hole.

Regardless of the sport, the point is that you must know and consider the sport you are photographing to key in on the action that sells that sport. You must anticipate the action and squeeze the shutter a split second before the receiver catches the football. By

Figure 12-22.—Good action photograph using points of interest.

(Photo by JOCS (AW) Jon Gagné)

anticipating the play, you can capture the reception, rather than what happened immediately after the catch.

Shoot plenty of film when you cover sports. Often a shot you think will be good turns out to be unusable, while one you think you missed will run on the first page of the sports section.

People

Amateur Navy athletes are personalities within their communities. Your audience enjoys reading about them and seeing their photographs in your newspaper. Because the players are personalities, you should photograph them so they can be recognized in the picture.

The best sports photographs identify key players. “Identifying the players” means presenting the athlete from a profile to full-frontal view, if possible, to show the number on his uniform. A three-quarter to full-frontal view is best but is not always available.

SPECIAL CONSIDERATIONS FOR POPULAR SPORTS

Each sport has some peculiarities you must consider when you cover it. In the following text are some tips that will help you cover the “big three” sports—softball/baseball, football and basketball.

Softball/Baseball

If you make the proper arrangements with the base/station sports director, you can take photographs on the field in foul ground. However, as a courtesy, you should still ask the home plate umpire for permission.

Photograph left-handed hitters from the third-base side; conversely, right-handed hitters are best covered from the first-base side. You should shoot right-handed pitchers from the third-base side and left-handed pitchers from the first-base side. In softball, both left- and right-handed pitchers throw the ball while facing home plate, so you can shoot on the other side of the backstop or from directly behind home plate.

Home plate action is best shot from the third-base side of the field. Exercise caution, though. If you get in the way, you will probably be unwelcome at future games.

Get a variety of angles by moving around—go up in the stands, lie on the ground, look over a shoulder, or use any other creative angle that will not interfere with others.

Because you may need to photograph key plays on the opposite side of the field from where you are standing, be sure to use lenses with a long focal length.

Football

If you are covering **your** station or base football team, stay on that team’s side of the field and follow the action from that location. (In an assignment where you are covering both teams equally, you may move to the other sideline at the appropriate time.) Move up and down the field with the action and photograph the players as they run, pass, kick, tackle and score.

Football photography focuses on the offensive and defensive lines and the star players making or breaking plays. The end zones provide you with an excellent opportunity to capture plays on both sides of the ball. Since scoring takes place in the end zones, a lot of heated action and exchanges take place inside the 10-yard-line. On the sidelines, bench shots sometimes dramatically tell the winning or losing tale—the frustration painted on a coach’s face or the fatigue illustrated in a lineman’s slumped body.

Use long, fast lenses to cover football. Additionally, you should also have a wide-angle or normal lens for sideline and goal-line shots (fig 12-23).

Basketball

Basketball action normally takes place within 18 feet of the basket. Position yourself near your team’s basket so you can capture plays in the “lane.”

A 50mm lens is a safe bet for basketball photography. Longer lenses can make for dramatic

Figure 12-23.—An award winning black-and-white sports photograph captures the touchdown.
(Photo by PH2 Christian Fuchs)

photographs, but following the action and focusing becomes more difficult. However, you may get good shots by focusing a long lens on the net; then wait for a lay-up or rebound.

“Hoops” is perhaps the most difficult sport to photograph because of the lack of lighting, the fast action and the inability to always predict where the action will take place. To compensate, you should use a high-speed film or an electronic flash unit. Direct

flash creates harsh shadows and could blind the athletes, so use a diffused flash.

RECORDING OUTLINE INFORMATION

Sometimes events in a game happen so quickly that you cannot stop to write down outline information. In this case, it is sometimes wise to shoot the scoreboard, especially after a key play. Doing so can keep you on track if you cannot keep a running caption log to record the time remaining and score when the play occurred. Use time-outs, breaks between innings or other slack times to go back and write down your notes as described in chapter 9.

FORWARDING PHOTOGRAPHS

LEARNING OBJECTIVE: *Identify the process of handling photographs with historical or news value.*

Whenever a photograph is considered to be of historical or news value, the Navy Imaging Command in Washington, D.C., wants to retain it in the Navy’s permanent files (after you have made local use of it). Photographic documentation accomplished by designated photojournalists (NEC-8148) and other photography of significant news value should be forwarded to CHINFO.

Detailed instructions for handling photographs of this nature are covered in the *Navy Visual Information Management and Operations Manual*, OPNAVINST 5290.1.

CHAPTER 13

BROADCAST WRITING AND RADIO OPERATIONS

In the preceding 12 chapters, we covered the subjects that comprise roughly two-thirds of the journalist rating—print journalism and photography. Now we will examine the electronic media, beginning with the radio medium.

Although many of the techniques to be addressed also apply to television (chapter 14), our emphasis in this chapter is on radio and the unique writing, announcing and technical requirements of which you must be aware.

THE BASIC ELEMENTS OF RADIO

LEARNING OBJECTIVE: *Identify the basic elements of the radio medium.*

To use radio effectively as a Navy Journalist, you must remember the following one essential fact and be constantly guided by it: **radio is a medium of sound** (fig 13-1).

While people might hear without trying, they generally do not listen without being stimulated. Consequently, your job will be to stimulate them—to trigger their imagination so they can picture the event being described which is a necessity for an attentive radio audience. To do this, you must use one or a combination of the following three basic elements:

- Voice
- Sound
- Music

VOICE

The most important element of radio is voice, because it is generally the element used specifically to reach the listener with the desired information.

SOUND

When used on radio, sound must be distinguished easily so the listener is able to interpret the sound and understand what is being conveyed. The roar of a jet

Figure 13-1.—AFRTS radio broadcasters.

engine and the muffled sounds of other flight deck activity will help the listener to visualize the scene.

MUSIC

Music has a great suggestive power because it plays on human emotion and colors scenes. It touches the heart and mind and sets a desired mood.

When properly used, these three elements should accomplish the following three distinct purposes:

- To attract immediate interest
- To maintain that interest through a particular presentation
- To satisfy the audience's attention and curiosity

RADIO WRITING TECHNIQUES

LEARNING OBJECTIVE: *Recognize the six basic radio writing techniques.*

Radio writing techniques are designed to capture and hold the audience's attention until you have delivered your message. These six techniques are as follows:

- Aural sense appeal

- Rapid getaway
- Power of suggestion
- Pacing and timing
- Freedom of movement
- Conflict

AURAL SENSE APPEAL

Radio depends entirely on the ear; it must work completely on the listener's mental image inspired by sound waves coming from the radio speaker.

RAPID GETAWAY

Radio material must capture the attention of the audience within the first few moments of presentation or listeners will be lost. The material must present a challenge, a promise, a suggestion or a conflict to arouse the listener's attention.

POWER OF SUGGESTION

The human mind is a vast storehouse of scenery. The radio writer suggests to the audience what the scene should be and listeners —through their mind's eye —can see anything from a pinhole to Waikiki Beach.

PACING AND TIMING

You must prepare the material for delivery within a definite time frame. Within this time frame, the changes in quality, emotion, thought or feeling of the material are controlled.

FREEDOM OF MOVEMENT

As the radio writer, you can take listeners from one point on earth to another, or even into outer space with words, sound effects or the appropriate music.

CONFLICT

Radio writers call conflict the backbone of interest in radio writing. Conflict is the ageless formula of hero against villain, good against evil, the fight for survival and the solution to difficult problems.

RADIO NEWSWRITING

LEARNING OBJECTIVE: *Recognize the basic rules for radio newswriting.*

As a Navy Journalist your first encounter with radio writing will probably be as a radio newswriter. In that assignment your job will be to meet the deadlines and rigid standards of the electronic media with the Navy's news story.

Radio news style, while dictated by the need for getting and holding the attention of an audience, differs from station to station. It is alive and constantly changing along with the broadcast industry itself.

As with most areas of journalism, there are few absolutes. When scripting broadcast copy, you will face many subjective choices that can only be made by using your own common sense.

The guidelines presented in this chapter are intended to be consistent with the style recommended by The Associated Press. However, keep in mind that these guidelines are just that—guidelines. For your copy to serve any worthwhile purpose, it must be the kind of news story or radio spot the individual radio stations in your geographical area desire and are able to use. Most local broadcast stations have individual preferences regarding their newscasts and announcements. To be responsive, you must be willing to adapt to those preferences. Study the styles of the stations in your area. If your material does not meet the requirements of the stations you are attempting to serve, then make the necessary modifications.

Initially, be aware that writing for broadcast media is not the same as writing for print media. True, the same rules of accuracy, propriety and good taste apply; nevertheless, there are a number of differences, particularly in writing style. Your job is to tailor each release for the medium that will use it. A release sent to an area newspaper may be turned down by area broadcast stations if it is not rewritten in broadcast style.

Remember that any station is more likely to use your release if it is in a form that does not require the newscasters' reworking. Do not create extra work for the news outlet. This is a fundamental step and should be practiced by every public affairs office.

Broadcast writing is highly personalized—far different from writing for the print media. Broadcast copy is written and designed for the ear. It is personal and has a sense of immediacy. The listener becomes

involved and feels as though he is a part of the event being reported.

THE SIX Cs

In keeping with the requirements previously covered, your broadcast copy must measure up to the following six Cs:

- Clear
- Concise
- Complete
- Conversational
- Current
- Correct

Clear

Clear copy is written in a simple, easy-to-understand manner. It is developed in a logical way, flows smoothly and is easy for the listener to follow. Even the simplest story may be misunderstood on the basis of one hearing. The listener's attention may be divided between any number of distractions. Therefore, a radio news story should be perfectly clear to avoid misinterpretation.

Avoid jamming too many thoughts or numbers into one sentence. Generally, sentences that are more than 25 words contain more than one thought and should be rewritten into separate sentences. The same principle applies to dependent and independent clauses. They are often very cumbersome, so write them as separate sentences. Commonly accepted literary techniques, unusual words and complex phrases also tend to obscure sentence meaning.

In broadcast writing, simple words say it best. Choose words that everyone will understand—the announcer as well as the listener. Do not ignore colorful or descriptive words. However, steer clear of flowery phrases and trite expressions that simply take up time and are of no value. Avoid slang and always translate military, technical, legal and foreign terms into simple language.

Concise

You have concise copy when all unnecessary words have been trimmed away and only those words essential to convey your thoughts remain.

It cannot be overemphasized that broadcast writing is writing for the ear. Listeners do not have the opportunity of “rehearing” your copy, so your sentences should be direct and crystal clear. If your copy is long and involved, you put a strain on the listener and hinder comprehension. This does not mean broadcast writing should be kept at a fifth grade level—but given the choice of being complex or simple, you should choose the latter. Your obligation is to put information into meaningful terms that the “average audience” will understand, and more important, want to hear.

Complete

For the broadcast story to be complete, you must include in it at least four of print journalism's five “Ws.” Obviously, you will normally state **what** happened in your lead sentence. Then you will tell to **whom** it happened, **when** it happened, and **where** it happened. **Why** and **how** generally are not critical, although to be complete, some stories will require this information.

Conversational

Like good conversation, broadcast writing is informal and free-flowing. Write the way you talk. Let the story tell itself. This may sound easy, but it will take some effort in the beginning. A common pitfall is to write a story as it may have been required for an English composition or a print journalism assignment. Broadcast copy is read **aloud** by the announcer. It is not read by the listener.

The twofold objective of the conversational tone is that first, it allows the announcer to pick up the drift of the story and second, it makes the copy sound “right” to the audience.

A good broadcast writer “listens” to the story being written. When you have finished writing your copy, take it out of the printer and read it aloud to make sure it sounds conversational. Make sure there are no hard-to-pronounce words or combinations of words that are awkward to the ear. Rid your copy of words that might be unfamiliar to your listeners.

Current

If your story is not current, you do not have “hard” news. News of a perishable nature is usually hard news. If you have a story of immediate news value, you should expedite its completion and delivery to the

media. By the same token, if there are new facts or circumstances relevant to your initial release, an update of the initial story should be provided (and marked as an update). This will help ensure currency. It is also helpful if the new or changed elements of the story are identified to reduce possible confusion with information in the original release. You will feel the pressure of meeting deadlines, but remember your credibility is on the line.

Correct

The hallmark of journalism as a writing art—either print or broadcast—is the accurate presentation of facts. Your finished product must correspond accurately with the facts of the story. In the field, you will follow every possible lead to get the facts as well as report them.

COPY FORMAT

LEARNING OBJECTIVE: *Recognize the format used in broadcast copy.*

Normally, when you write copy for radio, you start with a general “what happened” lead followed by a body of significant facts. This body of information does not have to include **all** the facts of the story—only the most important ones. Radio writing is different from newspaper writing, because the most common newspaper lead is the summary lead (using the five Ws and H). For radio copy to include the who, what, where, when, why and how in the lead would be too cumbersome. There is no time for nonessential details in radio news items. For the most part, news stories run from 20 to 30 seconds. Spot announcements run from 10 to 60 seconds, and features may run for 2 or 3 minutes, depending on the topic.

THE BEGINNING

The lead sentence must gain the attention of the listeners and orient them on the facts that will follow in the body of the story.

When you begin a story with a person’s name or a number, you risk the possibility of that information escaping your listener. Have you ever wished that a newscaster or announcer would repeat something because you either joined the story in progress or did not initially give full attention to what was said? Some writers remedy this by repeating key information later in the story. Unless you are striving for special effect,

avoid names and numbers at the start. Do not use an “unknown” name at the beginning. It is much better to say, “A San Diego Sailor was cited for heroism today,” than to say, “Seaman Phillip Jones was cited for heroism today.” Start the story with a general “what happened” lead; then mention the recipient by name.

NAMES AND TITLES

In the case of names and titles being used together, titles should precede names. It should be “Hialeah Mayor Perfecto Hernandez—not ”Perfecto Hernandez, Hialeah Mayor.” Alert your listener to whom you are about to name by prefixing the name with the person’s title.

You should refer to federal office holders by title or as “mister.” For example, you would use “President Bush” or “Mr. Bush,” “Mr. Chaney,” or “Vice President Chaney,” “Senator Simpson,” or “Mr. Simpson.”

If a difficult name is unessential, use only the person’s title, such as “The Ambassador from Nigeria ...”

INITIALS

Generally, it is better to omit the middle initial of a person’s name unless it is a well-known part of the person’s name, such as Howard K. Smith, William F. Buckley or John F. Kennedy. In the case of president George W. Bush, the use of a middle initial is crucial so that he is not confused with his father, former president George H. W. Bush. The other exception to this rule is when the nature of the story requires further clarification, such as in births or deaths.

<u>USE</u>	<u>AVOID</u>
DISHONEST	NOT HONEST
INNOCENT	NOT GUILTY

<u>USE</u>	<u>AVOID</u>
FORGOT	DID NOT REMEMBER
IGNORED	DID NOT PAY ATTENTION
UNABLE	NOT ABLE

WORDS

In broadcast writing, you must be aware of certain categories of words that are potential trouble areas. These categories are explained in the following text.

Contractions

In day-to-day conversations, contractions are used rather liberally. Therefore, you should consider using contractions whenever possible because they add to the “conversationality” of your broadcast copy. A definite exception to this rule is the “it will” contraction “it’ll,” which is awkward when you are trying to read it into a microphone. Additionally, a contraction should not be used when you are intending to stress a particular word or phrase.

Not

Avoid the use of the word *not* in your copy. “Not” can be dropped out of your copy inadvertently and leave listeners wondering whether they heard “not.” Note the following examples:

Pronouns

There is a danger in using personal pronouns in broadcast copy. When you use “he,” “she” or “they,” make certain there can be no doubt in the listener’s mind to whom you are referring. The ear cannot go back and pick up the identification. Repeat the noun if there may be any question as to whom you are referring.

Alliterations

Beware of alliterations. When you compose a sentence consisting of several words beginning with the same vowels or consonants, you have an alliteration, and the announcer has a problem. Note the following examples:

Examples: THE WESTERLY WIND WHISTLED WILDLY.

THE LOVELY LITTLE LASSES LAUGHED LOUDLY.

Sibilants

Beware of too many sibilants ... “s” and “sh” sounds. They tend to create a hissing sound when read aloud. Read the following example aloud:

Example: THE SIX SOLDIERS STOOD SHOULDER TO SHOULDER.

This problem also arises quite often when the apostrophe is used to show possession. Remember, the sibilant makes the announcer sound like a “snake sliding slowly southward.”

Homonyms

Watch out for homonyms—words that sound alike but have different meanings. The ear cannot tell the difference between “won” and “one” or “bear” and “bare.”

Here and There

Where are “here” and “there” when they are heard by listeners scattered over a wide broadcast area? Make “here” and “there” taboo words when you must refer to a location. “Here,” in reference to a location, can be anywhere it is heard.

Libelous Words

So-called “red flag” words can lead to libel. You should be careful not to mistake “colorful treatment” in your story with words like Marxist, illegitimate, deadbeat, addict and so on.

Meaningless Words

When you refer to persons, places or things already mentioned avoid using meaningless words, such as “latter,” “former,” and “respectively.” Again, listeners cannot refer back. Likewise, avoid transitional phrases within your stories, such as “meanwhile,” “meantime” and “incidentally.” They are crutches. Each thought, phrase or paragraph should flow to the next with skillful organization—not with throwaway transitional words. Steer clear of flowery phrases and trite expressions that take up time and space and are of no value. Also avoid slang, vulgarisms and dialects in news writing.

Always translate military jargon and technical, legal and foreign terms into simple language as in the following examples:

USE	AVOID
ASSIGNED	DETAILED
BEFORE	PRIOR TO
ENLISTMENT	HITCH
IF	IN THE EVENT OF
SAID	CLAIMED
SENT	TRANSMITTED

Abbreviations and Acronyms

Abbreviations are used in broadcast copy, but only when they are intended to be read as abbreviations. The use of well-known abbreviations is permissible, such as Y-M-C-A, F-B-I, U-S, U-N, A-M, P-M or E-S-T (note hyphens). You may also use MR., MRS MS and DR. “ST.” may be used instead of “SAINT,” in cases such as ST. LOUIS or ST. PAUL.

Do not abbreviate the names of military installations. For example, use FORT (not FT.) KNOX and NAVAL AIR STATION (not NAS).

Never abbreviate names of states, cities, countries, political parties (except G-O-P), days of the week, months, titles of officials and address identification, such as street, avenue, drive or boulevard. In addition, avoid starting a sentence with an abbreviation.

A good rule for you to remember when using abbreviations in broadcast copy is—**when in doubt, write it out**. Note the following examples:

WRITE	AVOID
THE SENIOR BALL	THE SR. BALL
RALPH SMITH JUNIOR	RALPH SMITH JR
CAPTAIN KIDNEY	CAPT KIDNEY
AIRMAN HOMEY	AN HOMEY
SPECIALIST FIVE HILL	SP5 HILL
SEAMAN TURGEON	SN TURGEON
CHIEF PETTY OFFICER OTTO	CPO OTTO
PETTY OFFICER TINAI	PO TINAI
RADIO STATION W-I-N-E	RADIO STATION WINE
WORLD WAR TWO	WORLD WAR II OR WWII
80 MILES AN HOUR	80 M.P.H. OR 80 M-P-H
HAWAII	HI

When you use an unfamiliar abbreviation or acronym that will be pronounced as a word, be sure to spell it out in the first usage. The following example applies:

Example: THE NAVY’S CHIEF OF INFORMATION—COMMONLY CALLED CHINFO ...

Phonetic Spelling

If you are concerned about mispronouncing names and places, you can limit the possibility by writing a phonetic spelling of the word in parentheses immediately following the troublesome word. You are the author of the release and thus the “authority” for pronunciation of all names and places in the story. Study the following example:

Example: CAPTAIN ANTOINE (AN-TWAN) SPOKE TODAY...

Make sure the phonetic spelling appears on the same line as the word it represents.

NUMBERS

Numbers present special problems to the broadcast writer. For the sake of clarity, broadcasters have developed their own style with numbers. Any number that begins a sentence is always written out.

From One to Nine

For broadcast copy, write out the numbers from ONE to NINE. **Exceptions:** Sport scores, time (hours, minutes, etc.), dates, addresses, telephone numbers and license numbers.

From 10 to 999

Use numerals for numbers 10 through 999. **Examples:** 12, 45, 893, 250, 999.

Thousand, Million, Billion

Borrow from both styles and substitute words for zeroes. **Examples:** ONE-THOUSAND, 15-HUNDRED, 150-BILLION, TWO-TRILLION.

Conversational Numbers

Make numbers conversational. Round out figures unless the exact figure is essential to your story. For example, \$1,527 would become 15-HUNDRED DOLLARS. However, exact numbers must be used if your story deals with deaths or other subjects requiring exact statistics.

Dates

Write dates as OCTOBER 1ST, 2ND, 3RD, 4TH and 31ST, and use four digit numerals for years, such as 1979 or 1994.

Additional examples of using numbers in broadcast copy are shown in Table 13-1.

STRUCTURE OF BROADCAST COPY

LEARNING OBJECTIVE: *Recognize the structure of broadcast copy.*

Broadcast writing, like other styles of writing, can only be learned through experience. Consequently, writing experience can only be gained by writing, writing and more writing.

That is not to say there is nothing you can do in the meantime. To the contrary, there is plenty you can do to prepare yourself for success in this challenging field.

As an aspiring broadcast writer, you should study carefully, examples of good broadcast writing. In addition, as you begin to write, remember the principles and techniques covered on the following pages.

Writing for the ear can be tricky business. Reducing a complicated issue or concept into shorter and simpler terms is required of a good broadcast writer.

The most successful broadcast writers write the way people talk in their daily conversations. They write as if they were telling the story to a friend. As an experiment, start noticing the lengths of sentences

Table 13-1. —Using Numbers in Broadcast Copy

	<u>WRITE</u>	<u>AVOID</u>
Money	10-THOUSAND DOLLARS	\$10,000.00
Fractions	TWO-THIRDS	2/3's
	FIVE-TENTHS	0.5
	ONE AND SEVEN-EIGHTS	1 7/8's
Percentages	SIX PERCENT	6%
	ONE-TENTH OF A PERCENT	.1%
Address	4951 WEST 14TH LANE	4951 W. 14 LN.
Telephone Number	555-1212	5-5-5-1-2-1-2
Ages	12-YEAR-OLD MARY SMITH	MARY SMITH, 12
Decimals	11-POINT-25 or 11-POINT-TWO-FIVE or 11 AND A QUARTER SIX-POINT-FIVE or SIX AND A HALF	1.25 6.5
Roman Numerals	LOUIS THE 16TH POPE JOHN PAUL THE THIRD	LOUIS XVI POPE JOHN PAUL III
Ratings	THE NUMBER ONE TEAM	#1 TEAM
Scores	9 TO 4 23 TO 6	NINE TO FOUR 23 TO SIX
Odds	THREE-TO-ONE	3-1 or 3:1
License Plates	H-L-S 121	HLS-121
Military Units	SECOND FLEET	2ND FLEET
Height	FIVE-FEET-FIVE-INCHES	5 FT. 5 IN. or 5-5

used in normal conversation. You will even find that we do not always talk in complete sentences. Quite often we speak in fragments, especially if everyone engaged in the conversation is familiar with the subject matter.

Nevertheless, do not get too carried away with this idea. While the strict grammatical rules we have used during years of education might not have a direct application to broadcast writing, they are still valuable. Verb tense agreement and subject-verb agreement, in particular, are still important, especially for the sake of clarity.

PRESENT TENSE

Since broadcasters report events as they happen, the present tense is the natural tense. Using the present tense in broadcast news gives the copy an air of immediacy and it gives the listener a sense of participation. However, the verb tense that is most natural to a situation will be the most effective. Every story does not have to sound as if it happened the moment before the newscaster went on the air.

ACTIVE VOICE

Write your broadcast copy in the active voice. The active voice will help you tell your story more quickly and effectively. It also gives the story a sense of immediacy. Active voice provides impact, which is extremely important to a competitive broadcaster. On the other hand, the use of passive voice normally weakens the impact of a sentence. Look at the following example:

Example: THE MILITARY POLICEWOMAN
SEIZED THE EVIDENCE. (Active)

THE EVIDENCE WAS SEIZED BY
THE MILITARY POLICEWOMAN.
(Passive)

If you write the copy to sound like old news, then it will probably be treated as **no** news. Further, writing stories that will be happening far in the future is just as bad.

Do not confuse the active voice with verb tenses. The active voice can apply to past, present and future tenses. Active voice does not necessarily mean the present tense! **Subject-verb-object** is the best indicator of the active voice structure.

SENTENCE LENGTH

A sure way to improve broadcast copy is to shorten sentence lengths. Long sentences are difficult to understand and are equally difficult for an announcer to read. Remember, the announcer has to breathe! Further, the announcer's ability to breathe naturally will directly affect the pace and phrasing of the story. Again, the sentence has to sound natural. A good average length for broadcast sentences is 20 words. Do not go over 25 words. This is not a magic number, but it does work. Sentences longer than these tend to be saddled with unnecessary clauses or multiple thoughts. More often than not, those additional clauses can be treated as independent phrases. Broadcast sentences starting with "and," "but," or "because," for example, are perfectly acceptable as long as they sound natural.

You should vary the length of sentences also. Do not peg your sentences to that 20-word mark. Try to mix lengths. If all the sentences are the same length, the copy becomes very stilted and sounds like a laundry list. When possible, give the copy a little rhythm, a natural flow that approximates a conversation. The end result of proper sentence lengths is broadcast copy that stands a better chance of being understood by the audience.

THE LEAD

As stated earlier, the most important sentence in your broadcast copy is the lead. The lead should grab the listener's attention and set the tone for the rest of the information. Brevity and conciseness play an important part in the lead sentence. The general "what happened" lead is usually the most effective. This lead also can help localize the story. There are several reasons for the "what happened" lead. In broadcast copy, based on the premise of "headline service," there just is not sufficient time for you to deal with all the complexities of a story. Only one or two of the "Ws" might be dealt with at times. Granted, this may sacrifice some of the meaning of the story, but it is also a fact of life. Additionally, the broadcaster is usually working within a given time frame for a story. Some "stories" may be only 10 seconds in length; others may run longer. The copy is not edited by whacking off the last sentence, since the last sentence also is quite important to a broadcaster. The last sentence

is often used to make a specific point or as a wrap-up.

QUESTION AND QUOTATION LEADS

Generally, questions and quotations are not used in the lead of hard news stories. Since your listener cannot see the quotation marks, a quote requires special attention. A question lead, in other than soft news or a feature story, too often sounds like a spot announcement or commercial message.

The rule can be violated if your copy contains a rhetorical question that adds to the attention-getting nature of the lead, as in the following example:

Example: HOW COMMON IS THE COMMON COLD? A GROUP OF DOCTORS ARE LOOKING FOR THE ANSWER TO THIS QUESTION.

The same exception to this rule holds true in the use of quotations in a hard news lead, as in the example that follows:

Example: “WE WILL BE ON TOP OF INFLATION BY THE END OF THIS QUARTER.” THAT PREDICTION WAS MADE THIS MORNING.

THE BODY

After writing the lead to your broadcast story, you will develop the specifics of the story logically in the body of your story. Logical development is nothing more than an orderly development of the body of your story so that it flows smoothly to an end. Ask yourself, What is the next thing the listener wants to know?

The body of the broadcast news story can be developed in any one of the following three patterns: chronologically, expanding the Ws, and descending importance.

Chronological Development

In chronological development, you narrate the event from the beginning to its conclusion.

Expanding the Ws

Specifically identify the who, when, where, and so forth, and further amplify the “what happened.”

Descending Importance

After explaining “what happened” in the lead, place the facts in order of descending importance. Remember to place the most important facts first.

Avoid placing unnecessary details in the body of your story. Learn to separate the important from the trivial. Often, you will have to condense, to 100 words or less, a story that a newspaper might use as many as 750 words to report.

Quotations and Attributions

Earlier, we covered the use of quotations in your lead sentence. What about quotations in the body of your story? The same fundamental guidelines apply. Your listener cannot see quotation marks; therefore, you must alert the listener that a quote is coming up.

In the following example, the listener is alerted with “what he called” and “he said” before the quotes.

Example: THE SENATOR ATTACKED WHAT HE CALLED “NEEDLESS AND IRRESPONSIBLE USE OF FEDERAL POWERS.” HE SAID, “I BELIEVE THIS IS OUR MOST SERIOUS PROBLEM.”

QUOTE, UNQUOTE.—To lead into quotes by the use of “quote” and “unquote” is disconcerting and unconversational. Avoid the use of long quotes. If it is necessary to link the statement with the speaker, use conversational phrases for this purpose. Consider the following example:

Example: THE ADMIRAL WENT ON TO SAY ... CONTINUING HIS REMARKS, THE ADMIRAL SAID.

DANGLING IDENTIFICATION.—Generally, you should not start a sentence with a direct quote or paraphrase and tack its source on the end. This is known as a dangling identification or attribution. Remember to alert your listener that a quotation is coming up. Start the quote with the source. Consider the following example:

Example:

Correct—PRESIDENT BUSH SAID, “WE MUST CONTROL INFLATION.”

Incorrect—“WE MUST CONTROL INFLATION,” PRESIDENT BUSH SAID.

PUNCTUATION

Unlike punctuation for printed newswriting, punctuation in broadcast writing is used to help the announcer read the copy aloud. For example, a comma tells the announcer to pause, and a hyphen helps the announcer to pronounce difficult words.

The Period

As in any writing, the period indicates the end of a sentence or thought. More periods are used in broadcast writing because broadcast writing sentences are generally shorter and more conversational.

The Comma

Use the comma to indicate a pause shorter than that of the period. Do not use a comma unless you want the announcer to pause.

The Dash

Use the dash to set off appositives and other parenthetical expressions. Consider the following example:

Example: NATO—THE NORTH ATLANTIC TREATY ORGANIZATION—VOTED THIS MORNING.

The Hyphen

Use the hyphen to help announcers in phrasing difficult words and to instruct them on how to pronounce individual elements distinctly. Note the following examples:

Examples: RE-ADJUSTED, RE-EVALUATE, CO-OPERATE, RE-ALLOCATE, W-C-O-A, F-B-I, Y-M-C-A

The Dots

Occasionally, you can use a series of three dots to indicate a pause longer than that of a comma. The series of three dots can also be used for a dramatic effect. Consider the following example:

Example: THE JURY FOREMAN ANNOUNCED IN A CLEAR FIRM VOICE ... “INNOCENT!”

Parentheses

Normally, in broadcast copy, the material inside parentheses is not meant to be read aloud. Parenthetical material in broadcast copy includes notes to the announcer such as pronunciation guides, reading rates, and so forth.

Quotation Marks

Quotation marks often will appear in broadcast copy as a cue to the announcer or newscaster to stress a particular word or phrase, setting it apart from the rest of the sentence. Do not confuse the use of quotation marks as a cueing device with their use for indicating a direct quote. Quotation marks also can be used as an aid to announcers to set off nicknames, titles of books and plays and so forth. Note the following example:

Example: THE SQUADRON—BETTER KNOWN AS THE “FLYING BLUE DEVILS”—BEGINS ITS SIX-MONTH DEPLOYMENT TODAY.

MECHANICS OF BROADCAST WRITING

LEARNING OBJECTIVE: *Identify the mechanics of broadcast writing.*

There is more to a successful broadcast news release than a good news peg or interesting story topic. Your release may not even reach the news director’s desk if it does not comply with the mechanics of broadcast writing.

When we speak of broadcast writing mechanics, we are referring to all aspects of a news release, other than the actual content of the story. We speak of a basic format and style used by both commercial and military broadcasters.

Your compliance with a few basic rules assures a better chance for your release to make the airwaves and, in turn, tells the recipient of your story that he or she is dealing with a conscientious broadcast journalist.

Always treat a release from your office as official correspondence. You are responsible for the information it contains. In the broadcast copy, you should include all the facts necessary for the release to be understood and include all administrative information, such as points of contact and release numbers.

Stations will not accept or use sloppy copy. Your broadcast releases should be error-free. Since broadcast copy is designed to be read aloud, it should not appear to be cluttered. Make sure there is sufficient white space, and always type your script double-spaced. Double-spaced copy is not only easier to read but it also provides space for additional information the announcer might want to insert.

UPPERCASE VS. LOWERCASE STYLE

Broadcast copy can be written (typed) in all capital letters or uppercase and lowercase. There are merits for each style. We are used to reading in uppercase and lowercase, and the patterns of words are easier to distinguish. If both uppercase and lowercase are used, you can also use caps for emphasis. However, the wire services use all caps and the all-capital treatment would conform to that style. Your job is to determine the best style for your releases and use it. Sticking to one style only, within the context of a story, also is important. Be consistent!

TYPING COPY

When typing broadcast copy, you should set your typewriter/printer margin for an average of 60 spaces per line. This will give you about 10 words per line and will aid you in quickly determining how much copy you have written or need to write. Two to four lines will equal about 10 seconds of copy. Seven to eight lines will yield approximately 30 seconds, and 14 to 16 lines will average about 60 seconds.

Since the size of the print influences readability, your releases should be in 10- or 12-point type.

TIMING

Timing in newscasts is also very important. Many radio stations run a five-minute newscast on the hour. By the time all the spots, jingles and introductions are weeded out, there is precious little time for news. Ten or 15 seconds in story length can make a difference in whether or not your release will be aired. Your release should be timed, and the time required to read it should be indicated on the release.

The average announcer reads at a rate of 2 1/2 words per second. Simple multiplication shows a 10-second release averages 25 words and a 60-second story averages 150 words. Remember—we are referring to an “average” announcer; naturally, there

are many variables. Radio DJs usually read faster than radio newscasters, and radio newscasters usually read faster than television newscasters.

PARAGRAPHING

Do not indent sentences in broadcast copy. It is a waste of space when writing on only half a page. Paragraphing is not used in broadcast writing, since the treatment of a topic can usually be handled in one paragraph anyway. Always set margins flush-left, so your copy will appear as one block.

Consequently, you should not hyphenate or divide a word at the end of a line. If the whole word does not fit, simply drop down to the next line. Likewise, do not split a sentence between pages in your broadcast story. It makes it difficult for the announcer to maintain continuity.

NUMBERING PAGES

If your broadcast story is more than one page, number the pages consecutively. For example, if your copy is three pages long, number the first page 1 of 3, and the last page 3 of 3. Write page numbers in the upper left-hand corner of the page.

(MORE)

When a story takes more than one page, center the word (MORE) under the manuscript portion at the end of each continued page.

THE END

Indicate the end of your broadcast copy by centering three number symbols (# # #) under your manuscript column.

ADMINISTRATIVE INFORMATION FOR BROADCAST RELEASES

LEARNING OBJECTIVE: *Identify the administrative information required on broadcast scripts released to the media.*

For obvious reasons, it is necessary for you to identify yourself and your organization on broadcast releases. You should also include a telephone number in case the civilian broadcaster needs to ask any questions relative to the story.

FOUR-UNIT HEADING

Each broadcast script will have a four-unit heading, located below the administrative information but above the actual story matter. Though not read aloud, this heading tells at a glance the basic information the broadcaster requires in scheduling your story for a newscast. The four-unit heading contains the following components:

- **Slugline.** The slugline serves as a title or headline of the story.
- **Date.** The date on the script is the date of its release.

- **Copy length.** The copy length tells the recipient how long it will take to read your broadcast copy.
- **Release line.** The release line indicates the type of broadcast release (covered in the following text).

RELEASE LINES

All items submitted to radio stations should contain specific release information. One of the following release methods is recommended:

- **FOR IMMEDIATE RELEASE.** Use on hard news items.

SAMARA HELICOPTER CRASH KILLS FOUR (Slugline)	(Release Date) July 21, 2002
30 SECONDS (Copy Length)	(Release Line) FOR IMMEDIATE RELEASE
<p>A MILITARY HELICOPTER CRASHED TODAY AFTER TAKING OFF FROM NAVAL AIR STATION SAMARA, KILLING ALL FOUR CREW MEMBERS ABOARD. THE S-H THREE-H “SEA KING,” ASSIGNED TO HELICOPTER COMBAT SUPPORT SQUADRON 297, WAS EN ROUTE TO A TRAINING EXERCISE ABOARD THE AIRCRAFT CARRIER U-S-S QUERINO (KAY-RINO) WHEN IT WENT DOWN AT THE NORTH END OF THE MAIN RUNWAY. THE NAMES OF THE DEAD ARE BEING WITHHELD PENDING THE NOTIFICATION OF RELATIVES. THE NAVY IS INVESTIGATING THE CRASH.</p> <p>###</p>	

- **FOR GENERAL RELEASE.** Use on soft news, features or spots that do not require immediate airing before its value is lost.
- **DO NOT USE AFTER (Time and Date).** Use on spots or news items about events that run for a limited time.
- **HOLD FOR RELEASE UNTIL (Time and Date).** Use on advance releases.

EDITING BROADCAST COPY

LEARNING OBJECTIVE: *Identify the method of editing broadcast copy.*

Unlike print journalism, in which copy usually passes through several reviewers, broadcasters do not usually exercise that type of control. Depending on the deadlines of the broadcast facility, they might rewrite your release entirely. On the other hand, the local newscaster could simply adopt the old “rip and read” policy and read your release “cold.” Naturally, the second method does not speak too highly of the news staff, but unfortunately, some commercial and military broadcasters continue to do this.

Absolutely clean copy—free of mistakes—is the rule for copy prepared for release to radio stations. Sloppy copy is disconcerting to any announcer.

For in-house productions, editing marks may be used sparingly, but only those editing marks easily understood by an announcer are acceptable. Do not use print media copy-editing marks. Use only the broadcast editing methods covered in the following text:

- **Correct misspellings** by blackening out the misspelled word completely and printing or typing in the correct version above it. Do not attempt to correct a letter within a word. Broadcast copy has no editing mark to correct a single letter within a word. Rewrite the entire correct word as in the following example:

- **Insert words or phrases** by printing or typing the desired words above the line and indicate

the point of insertion. Note the following example:

- **Separate run-together words** by using a single line, as shown in the following example:

- **Delete a word** by blackening out the word and bridging the gap. Consider the following example:

- **Delete words on more than one line** by using a curved line to reconnect, as shown in the following example:

SPOT ANNOUNCEMENTS

LEARNING OBJECTIVE: *Identify the two types of radio spot announcements and recognize the techniques used in writing them.*

The sustaining point of a commercial radio station is the commercial. Although neither the Navy nor the American Forces Radio and Television Service (AFRTS) use them, commercials have a valuable counterpart in Navy public affairs. That counterpart is the spot announcement. Table 13-3 shows a basic spot announcement format.

Spot announcements are usually 60 seconds or less and come in two forms—the selling spot and information spot. Both are covered in the following text.

PROGRAM 76 WORDS

RELEASE NO. 54-02

RADIO SPOT FORMAT

September 4, 2002

30 SECONDS

FOR GENERAL RELEASE

AMERICANS HAVE GROWN UP WITH COMMERCIALS AND SPOT ANNOUNCEMENTS. THE “SELLING” SPOT INFORMS THE LISTENER, THEN TELLS HIM TO DO SOMETHING. THE “INFORMATION” SPOT SIMPLY INFORMS. THE SELLING SPOT HAS THREE STEPS...ATTENTION, APPEAL AND ACTION. THE INFORMATION SPOT USES ONLY ATTENTION AND APPEAL. THE ACTION STEP IS WHERE YOU TELL THE LISTENER TO DO SOMETHING. IT CONTAINS SIX WORDS OR LESS. NONE OF THE OTHER SENTENCES...IN EITHER SPOT...SHOULD BE MORE THAN 15 WORDS.

#

SELLING SPOT

The selling spot is designed to make the listeners take some type of action as a result of the ideas you present to them. The spot also can be used to change attitudes. Examples of these are “Be there!,” “Do it now!” and “See your recruiter today.”

There are many ways for you to structure the selling spot. One way is the three-pronged approach—**attention**, **appeal** and **action**. First, you form your basic idea and attention-getting lead sentence. Then you present the merits, advantages and

appeal of the idea. Finally, you motivate your listener to take action to gain the benefits you were promoting in the spot announcement.

Attention

A lead such as “Now you can lose weight while sleeping!” is almost an automatic attention-getter for a large segment of your listening audience. This type of lead draws the listeners into your message by provoking their interest and attention. Copy directed toward emotional and motivational drives is copy that

sells and should be slanted toward a particular group that needs a particular product.

Spots selling baby food, for example, are directed at mothers who are concerned with the health of their babies. These spots emphasize the healthful ingredients of the baby food. In the same way, the slant toward a particular group is used by the Navy in recruiting. Such spots are aimed at young people in the age group between 17 to 25, and words, such as security, travel, education, missiles and electronics, are used as attention-getters.

When the attention portion is directed toward the listener's desires, aspirations, dreams and ambitions, you will take the first step toward getting that individual to listen to the appeal and the action portions of your spot.

Appeal

"Why don't you begin to enjoy the finer things in life?" You have probably heard that appeal in one form or another. In the appeal portion, you present the selling material—the message you want to convey to the audience. One thing for you to remember is to

AIR SHOW	November 9, 2002
30 SECONDS	FOR GENERAL RELEASE
	(DO NOT USE AFTER 11 A-M NOVEMBER 14)
 TWO SPECTACULAR AIR SHOWS ARE SCHEDULED THIS WEEKEND AT THE SAMARA NAVAL AIR STATION. THE EVENTS ARE BEING STAGED NOVEMBER 13TH AND 14TH AS A SALUTE TO AMERICA'S VETERANS. THE NAVY'S WORLD FAMOUS "BLUE ANGELS" WILL HEADLINE BOTH SHOWS. INTERESTING STATIC DISPLAYS AND EXCITING AERIAL ENTERTAINMENT ARE IN STORE. THAT'S SATURDAY AND SUNDAY AT THE NAVAL AIR STATION SAMARA. THE SHOW BEGINS BOTH DAYS AT NOON...AND ADMISSION IS FREE. COME EARLY AND SEE IT ALL. ###	

avoid cramming too many points into a short announcement. Keep it simple and stay with the subject.

For example, if you start off talking about travel as the attention-getter in a recruiting spot, do not drift off into education or some other subject in the same announcement. Another word of caution—do not promise the impossible. Be sincere and honest with your audience.

Action

“Buy U.S. Savings Bonds each payday.”

“Learn how you can travel the world with the U.S. Navy.”

These statements invite action and tell the listeners what they can do. The action step gives the listener a definite course to follow. The step should be forceful, combining invitation and demand, and it should compel the listener toward a positive action. Remember, the action step is designed to motivate the listener to buy, join, write or perform according to the action you have suggested in the message.

The success of any spot announcement as a selling device is measured by the listener’s response to the product advertised. Table 13-4 shows an example of a selling spot announcement.

Information Spot

The information spot is designed purely to inform. In this type of announcement, you are not trying to get the audience to do anything or to change attitudes. You simply want to give them information.

The information spot differs from the selling spot in purpose and structure. In writing the information

spot, you begin with **attention** and follow it with **appeal**. Because no response is desired from the audience, you have no need for an action step. Your job is to compose the message in a clear, concise form and to get the maximum amount of interesting information into the brief 10, 20, 30 and 60 seconds you may be allotted. Table 13-5 shows the information spot announcement.

SPOT WRITING TECHNIQUES

In writing either a selling or information spot announcement, you should remember the following four techniques that will pay dividends in quality:

1. **Plot the pitch carefully.** Before you put a word on paper, you have to know the type of audience you want to reach. If the audience is in the lower income bracket, gear the spot to the special needs and wants of this group. One approach could be the economic security angle; another is the “get-ahead-in-the-world” appeal. On the other hand, audiences in small rural towns might find the travel theme exciting and interesting. Spot writers must study prospective audiences if they are to be successful at communicating with them.

2. **Look for new target audiences.** Although the stress in writing may be about recruiting, you should be prepared to write spots that will sell the public on attending a command public visitation, a parade or a demonstration. These special events appeal to many audiences. Some spots might be directed toward fathers, children, teen-agers or even to mothers in the audience.

3. **Develop a direct, personal writing approach.** Even though the audience may consist of several thousand people, the copy is directed at one person.

Table 13-5.—30-Second Information Spot Announcement

###	

Make that individual feel that the message is personal. Address the listener in terms of “you,” “you’ve,” “your” and “you’re.” Always refer to the listener in singular form and in a friendly manner.

4. **Select words carefully.** Write spots in the active voice with such positive and colorful verbs as follows: go, see, take, try, get, visit, ask, call, be and buy. Be conversational, but avoid slang. Keep your words simple, and do not try to impress the listener with an extensive vocabulary. Speak to the listener in the language that person knows. You also should avoid special military terms and abbreviations that are unfamiliar to the listener.

Format and Preparation

Whether you are writing a spot announcement for an NBS detachment or a local commercial station, you should adhere to the following general rules concerning format and preparation:

1. **Follow the appropriate style.** Write your spot following the style guide of the station. A station manager might reject your spot if it is not in the style his announcers are used to reading.

2. **Submit clean copy.** All announcements you submit to radio stations should be free of errors.

3. **Submit the proper number of copies.** Check to see how many copies of an announcement each station needs.

4. **Meet deadlines.** If a station manager asks you to have a spot at the station by a given time, do not miss the deadline. Your violating this rule is the best way for you to keep your copy from ever reaching the airwaves.

Timing the Spot

Timing is extremely important in spot writing. On commercial stations, you will be competing with other public service agencies for free airtime. Naturally, a station can allot only so much time for public service announcements.

If you use music or sound effects in your spot, you must remember to take these into consideration in your timing. A 30-second spot with 10 seconds of sound effects averages four to five lines of copy. A stopwatch will help you in timing spots.

Whenever you write a spot, it is best that you include a “kill date” and cutoff time so the station will know when to stop using it. A spot heard over and over, day after day for a long time, soon gets dull and

irritating to the listener. Also, if you have a spot telling people to visit your command on Sunday, it would certainly sound ridiculous to hear it the following Monday.

RADIO ANNOUNCING

LEARNING OBJECTIVE: *Identify the techniques used in radio announcing in terms of preparing and delivering copy, and the responsibilities of the announcer.*

Some Navy broadcasters forget that their primary responsibility is to communicate. It is essential that you, the announcer, know what the stories are about before you try to read them on the air. Announcers who only read words are doing exactly that—reading words and not communicating. Remember—it is not the listener’s responsibility to interpret what is read.

PREPARING RADIO COPY

There are certain aspects of preparing your radio copy that you must do before you go on the air. These include phrasing and marking your copy.

Phrasing

The bulk of the communication process centers on phrasing. People do not talk in words; they speak in phrases. The phrasing process is done during normal conversation, without thought. Beginning newscasters have some trouble transferring this natural process when delivering their copy. The best way to see if your broadcast copy is divided into phrases is to read the copy aloud. Identify whether the phrases answer one or more of the five Ws and H. If the phrase does not answer one of the five Ws and H, then it is not a complete thought.

Marking Copy

Broadcasters use specific oral punctuation marks to divide their copy into phrases. There is disparity between written punctuation and oral punctuation. English teachers teach written punctuation and follow strict rules of usage. Oral punctuation adds accent and tells the announcer when to breath, without disrupting the natural flow, phrasing and the importance of a sentence.

As stated earlier, most phrasing problems occur because announcers do not understand what they are reading. They are not breathing at the right time or not

Tsble 13-6.—Radio Copy with Oral Punctuation Marks

marking their copy properly. Most announcers adapt easily to the following system:

/The single slash mark means you are to pause and take a short breath.

Use the single slash as an oral comma, just a short pause in the flow of words from your mouth—not a complete stop like a period.

//The double slash mark means you are to stop reading and take a deep breath.

The double slash is an oral period. This is a big stop and is the end of a sentence. This is the time to take a good breath for the next sentence.

///The triple slash mark means you are to pause for emphasis, but do not breathe.

This mark has nothing to do with breathing. It is just a sign to you, and it means pause for emphasis. You might use it for difficult names, quotes or a number in the copy you know you want to emphasize.

An example of radio copy with oral punctuation marks is shown in table 13-6.

When you are marking copy, make sure you do not change the meaning or context of the story. However, most stories may be marked in more than one way without changing their meaning. How you mark them will depend on your personal style.

DELIVERY

The way you speak or imply the meaning of a word may change the whole context of that story. You, the announcer, are the most important element in the information process. The fewer barriers introduced in transmitting the information, the clearer the

information is received and understood by the receiver or listener.

Variety

The announcer should have a voice that conforms easily to the spirit and intention of the assignment. No matter what the subject or script, the announcer must inform the listeners of his sincere belief in the content and the natural excitement (vitality) of the occasion. All meanings should be clear. Being bored should not detract from natural vitality. All the slight changes in mood and feeling, directed by the words and situation, have to occur as effortlessly as they do in speaking with a close friend. Discreet changes in the voice appear naturally when they are truly felt by the announcer.

The human voice is able to reflect all conceivable traces of mood and meaning. Subtle natural changes in vocal pitch, time, quality and force make this possible. Speech without thoughtful distinction tells only a shade of the full mood and meaning and may express monotony or give inaccurate information to the listener. The announcer should feel the mood and know word meaning if he is to show sincerity in his voice.

Articulation

In conversation, we naturally drop sounds and slur words. The reason for working on articulation is to make the sounds of words clear, so that the announcer may be understood.

Clean articulation is the most difficult aspect of voice and diction. Its intent is not to eliminate accents and regionalities, but to enable the announcer to communicate with everyone.

The following are a few drills and methods for dealing with some common articulation problems.

MUSHY SOUNDS.—If your speech sounds sloppy, chances are, you are not opening your mouth enough. Have another person watch you read or use a mirror. Notice if your lower jaw moves. If it does not, this could be the cause of the problem. Announcers who tuck their chin into their chest to make their voice deeper are creating articulation problems. Read your copy overemphasizing the lip, tongue and chin movement required to make each sound, then reread the copy normally. Keep your script at eye level and keep it up while reading so you cannot tuck in your chin.

The same theory applies to the announcer who does not move his lips. Read the copy, overemphasizing each lip movement, then read your copy again normally.

Another solution for mushy sounds is the “pencil method.” Place a pencil sideways to the back of your mouth and firmly between your teeth. Take your script and slowly read it through, articulating all the words. Then reread your script again normally. This will help you correct any mushy sounds.

DROPPING SOUNDS.—The ends and the middle sounds of words are commonly eliminated in speech. You should pronounce carefully each syllable of each word, overstating each sound. Then say the word normally.

Examples: stand-ing/standing (not “standin”)
work-ing/working (not “workin”)
help-d/helped (not “help”)
mix-ed/mixed (not “mix”)
spa-ed/sped (not “speh”)
tah-t/tot (not “tah”)
nah-t/not (not “nod”)
mos-t/most (not “mos”)
de-vel-op-ment/development (not “develoment”)
gov-ern-ment/government (not “govment” or “government”)
syl-a-ble/syllable (not “sylble”)

NEW ENGLAND “R.”—Announcers with this problem change the “R” sound in “car” to an “ah” sound (cah). The “ah” sound is easier to say since it does not involve moving the lips or the tongue. Read

several words with “Rs” in them, being careful to hit the “AH UR” sound. Try the following example:

Example: Parker parked the car outside the card store.

SOUTHERN VOWEL DISTORTIONS.—Some people from the South have a drawl that makes their speech difficult to understand. They hold the vowel (a, e, i, o, u) sound so long that it slurs into the next sound. For example, “I’m” becomes “Ahhh’m.”

To correct this, clip the sound and make it shorter. Run through the following examples, carefully articulating each sound.

Examples: just (not jist) get (not git)

for (not “fer”: replace the word on your copy with the word four or the number 4)

to (not ta: replace the word on your copy with the word “two”)

style (not “stahl”: I’m going to get just two styles of paper instead of getting the four styles you asked for.)

THE “S” SOUND.—The “S” sound is the most difficult sound to correct. The general rule is: do not mess with an “S.” Take the microphone and place it out of the “S” air zone, so when you talk, you are talking across the microphone instead of directly into it.

Rate and Transitions

Changes in the tempo (rate/speed) and the use of pauses (transitions) while speaking are essential to understanding. Normal speech rate varies from 80 to 175 words per minute.

A steady rate of speed will produce monotony. In general, changes of rate help reflect the weight of the issue. Important information is slowed; less important topics may be increased in speed.

As stated earlier, the oral punctuation mark gives the announcer an opportunity to pause. The pause makes the division of thoughts and the segmenting of those thoughts possible. Without the vocal pause, the meaning of the topic would be haphazard and hard, if not impossible, to follow. The oral pause also gives the announcer time to restore his breath supply naturally.

Authority

Announcers, and in particular news people, require authority in their voices. It is that special

something that tells the listener, “What I have to say is important.” Newscasters either have it (authority) or they do not—there is no substitute. In some cases, because of a naturally higher pitch, women newscasters may suffer from authority problems more than men, but it is not a problem unique to women.

The following techniques may help if you are lacking authority in your voice:

- **Take charge.** You must have a thorough understanding of your copy. It is up to the newscaster to tell his audience what it needs to know. You must adopt an attitude of, “This is important—listen to me!”
- **Add volume.** Intensifying your vocal tone to establish a sense of authority may be effective. Try this by standing about 10 feet from a wall. Deliver your copy loud enough so that your voice hits the wall and is reflected back. You do not have to yell, but you should be loud enough to be heard clearly 10 feet away. This is called vocal projection.
- **Monitor your volume.** Have another person stand across the room from you as you read the copy. Every time your volume drops, have that person tell you to speak louder.

Stumbling

All newscasters occasionally stumble over a word, and they should not worry about it as long as it is only occasional. When you experience a lot of stumbles, the cause is usually the brain getting ahead of the mouth. Here are a few solutions:

- **Concentrate on what you are reading.** Your mind should be on your copy and nothing else. Avoid distractions.
- **Use the index card technique.** If you are a speed reader or read unusually fast, place a 5- by 7-inch index card on the line you are reading. As you come to the end of that line, move the card to the next line. This technique will slow you down enough so you do not over-read and it will help you focus your attention on the line you are reading.
- **Use parentheses to mark any phrases that give you trouble.** Do not mark individual words—only mark the phrase.
- **Preread your copy at least twice for familiarization.** If your copy surprises you

while you are reading it on the air, you are not ready to read. You should be able to tell, in rough form, what the stories are about without looking at the copy.

- **Avoid backtracking to correct a stumble.** Keep going and do not call attention to the mistake. Some people worry so much when they make a mistake that they make additional mistakes. Once a mistake is made, **FORGET IT.** Concentrate on what is coming, not what is gone. Your audience does not expect perfection. (One exception to this rule is if the stumble changes a fact in a story. If this happens, take a second or two to regroup, then correct the error. You also can correct the error after a spot break, if time allows.)
- **Have your eyes checked by a doctor.** Unfortunately, eyesight deteriorates with age and even the best announcers cannot read words they cannot see.

Speedy Delivery

Speaking too fast is a common problem for beginning announcers. As the announcer, you can correct this problem by understanding that not everyone is able to think as fast as you can talk. If the listener cannot understand you because you are speaking too fast, then you are wasting the listener’s and your own time.

The following are a few simple tricks that will help you slow your delivery:

- **Write the words *SLOW DOWN* all over the margins of your copy in a bright-colored ink.** This will remind you throughout the newscast to keep your speed under control.
- **Use the three-step reading system.** Read the copy through once, as fast as possible. Then read it as slowly as possible, over-articulating and reading one word at a time. Finally, read the copy somewhere between the two previous speeds. During the third reading, make sure you are in the presence of someone who can tell you to slow down when you start to pick up speed.
- **Follow the “five-minute rule.”** The average rate of delivery is 15 lines per minute. The actual rate should be somewhere between 14-16 lines per minute. Limit yourself to 60 lines of copy for a five-minute newscast. Make sure you finish at exactly the five-minute mark. The only way to

reach the time mark and not have dead air is to slow down.

- **Use the eraser technique.** Place a medium-sized art eraser between your front teeth. Try to read the copy while holding the eraser firmly in place by biting down. You must articulate and be able to be understood while you are reading. It is almost impossible to talk fast and still be understood while you are holding the eraser.
- **Mark your copy for breathing points.** Breathe wherever you see a mark.

ANNOUNCER RESPONSIBILITIES

As you can tell, radio announcing is hard work. The listening audience may associate the word *glamorous* with the broadcast industry, but the fact is—radio (like television) is an exacting business and announcing emphasizes professionalism.

For every announcer who has made it to the “big time” and who has become a celebrity in the civilian world, there are 100 good announcers who, in addition to their on-air time, perform many other station duties. There are announcers in a lot of small stations who work the audio consoles, write last-minute commercials, rewrite news copy, check equipment and do anything else required of them to make the station work well. This is exactly what will be asked of you as a Navy broadcaster—you must be a **generalist**.

Furthermore, during your on-air experiences, you will realize that an isolated slip or flubbed line is almost inevitable. This is true even for the veteran announcer. However, if you make too many errors, you will be looking for a new job. The key to success is experience, and a good announcer drills diligently in the never-ending quest for perfection.

Required Qualities

The qualities usually considered necessary in a professional radio announcer are a good voice, little or no regional accent, clear diction, and accurate pronunciation. Quite often, your voice affects the audience’s opinions about programs.

A resonant voice, the best diction, and even the best pronunciation will not help the announcer who mechanically reads lines and fails to project a feeling of sincerity. In effect, the announcer must have a good radio personality and make his voice reflect such.

Adaptability

Your personality is reflected in your voice. If you are not genuine, the listener will take note quickly. Changes throughout the program day make it essential that an announcer be capable of changing his delivery to fit the content and mood of the particular program.

No matter the type of program or its theme, most listeners enjoy hearing a voice that offers friendliness, naturalness, sincerity, integrity and vitality. Announcers, of course, usually seek to work in an area where they perform best. Some announcers are best at news, some at country and western music, some at rock ‘n’ roll and so on. In short, you must be like a chameleon. You must be able to conform to the many variations of style that the average broadcast day will demand of you. You should set high standards for voice control, diction and pronunciation; then strive constantly to live up to those standards. This is a never-ending, ever-learning process. However, the satisfaction you will get from being an effective announcer is well worth the effort.

PRODUCING A RADIO FEATURE

LEARNING OBJECTIVE: *Identify the elements needed to produce a radio feature.*

In radio, you are primarily responsible for all stages of feature production. In commercial radio, particularly in smaller markets, the DJs of the station are responsible for producing features. The same thing applies at NMC broadcast detachments. Once you are assigned a production, the entire process, from researching the subject to putting it on tape, belongs to you.

In this section, “radio feature” and “audio production” are used interchangeably.

SELECTING MUSIC

Music is used to set the mood for a production. It can create a feeling of excitement, tranquility, suspense or sadness. The following four types of music can be used in audio production:

- Theme
- Background
- Bridge
- Fill

Theme

If you are doing a series of spots on a particular subject or using a particular character, theme music will lend identification to that subject or character. Avoid using familiar songs as themes; for example, “Gonna Fly Now” from the Rocky movie series or the theme from a popular television show. These selections tend to distract the listener and ultimately lessen the effect of the message.

Background

Background music helps set the mood of the feature production and it increases audience appeal. A voice-only production can be very boring, especially if it is just one voice. For example, a few strains of dramatic fanfare might heighten listener anticipation of a story climax. Conversely, you could use light, melodic music to support a comical subject. There is instrumental music to fit almost any mood. It is just a matter of listening to the selection, perceiving the emotion or mental image it creates and matching the appropriate mood to your subject.

When you are selecting background music, for instrumentals are preferred over music with vocals. Vocal songs tend to distract the listener from the message of the production. Vocal music may be used, but only if it contributes to the message. When vocals are used, level balance becomes critical so that the music does not override the message.

Background music should be unrecognizable and match the subject. By adding the right background music, you add to the aesthetic appeal of the feature.

Bridge

Bridge music connects or “bridges” two ideas or thoughts. Bridge music, also called transitional music, was used in radio theater to change the scene. A short instrumental fanfare can signal a change in topics or, a new scene can be introduced with a short musical theme that suggests a particular location.

Fill

Fill music is often called “pad” music and is usually an unrecognizable instrumental song. If your feature production is required to be a certain length, you can use fill music to eat up time at the end. This also allows the person airing the production an

opportunity to transition to the next program element gracefully with less chance of lapsing into dead air.

SELECTING SOUND EFFECTS

The use of sound and sound effects works much the same way as music. The purpose of sound effects is to enhance the spoken word.

Creative use of sound can help develop a vivid picture in the mind of the listener. The success of an audio production often depends on the mental picture conjured up by different sound effects. Good examples are the spots produced for the Radio Ad Bureau promoting radio advertising. By using sound effects, the producer created a visual picture in the listener’s mind by doing such things as draining Lake Michigan, filling it with chocolate, and topping it off with a 750-foot mountain of whipped cream and a 10-ton maraschino cherry. This versatility is available for any radio production and is limited only by your imagination and ability to locate or create sound effects.

The following are the three main types of sound in audio production:

- Real
- Simulated
- Prerecorded

Real

Real sound effects are produced in the studio using the actual source, such as papers shuffling or scissors cutting cloth. You are limited to the availability of the particular item to make the desired sound.

Simulated

Simulated sound effects are those that do not recreate reality, but merely suggest it. Crinkling cellophane can suggest a campfire, and running your thumb across the teeth of a comb can suggest casting a fishing line.

Prerecorded

Prerecorded sound effects are those available on tape or compact disc (CD). The two types of these are the ones that create a sound picture, such as a city street or factory, and the ones that create individual sounds, such as footsteps or the opening of a door. When using prerecorded sound effects, you are limited to the

recordings available in the tape or CD library of your station.

USE OF THE VOICE

The voice is the essence of most radio productions, because it conveys the message. Each announcer interprets copy according to his style of delivery and the type of delivery needed to communicate the message effectively. Voice characterizations may be used if it is appropriate to the production, but make sure the characterization is realistic and portrayed well.

BASIC PRODUCTION CONCEPTS

There are many ways to put an audio production together. The technique you decide on will depend upon the complexity of the production, the equipment available to you and your ability to put it all together.

Although there are many variations to the process, audio productions usually are formed around the following four basic concepts:

- Beginning to end
- Prerecorded voice
- Prerecorded music and sound effects
- Segmenting

Beginning to End

When you are using this method, everything is done nonstop, mixing all the elements onto tape. This means recording the narration, background music, and sound effects at one time, as they are called for in the script. Because this method requires many rehearsals and considerable production skill, it is not recommended for the inexperienced broadcaster.

Prerecorded Voice

If you choose the prerecorded voice method, put one element on an audiotape cartridge (known in the industry as a “cart”) and mix the other elements in as you go. This method is best used for a production that requires only a few supportive elements. The prerecorded element is the narration, allowing you to concentrate on mixing the other effects as they are needed. You can add other elements later.

A disadvantage to this method is that it limits the announcer’s flexibility to interpret the script as it relates to the accompanying music or effects.

Therefore, prerecorded voice is not the recommended method of production. It is used sparingly and, generally, only for “straight” copy requiring little interpretation.

Prerecorded Music and Sound Effects

Although time consuming, the prerecorded music and sound effects method works best in a complicated production, especially if the producer is inexperienced. By placing all the elements onto cartridges and then mixing them on audio tape, you can “build” sound elements by layering one element on another using multiple recordings. There are many possible combinations of cartridge-to-tape, CD-to-tape, or computer hard drive-to-tape. This method also allows the announcer to adapt the vocal mood to the mood created by the other elements.

Segmenting

The segmenting method allows the broadcaster to take manageable portions of the production and produce them using the beginning-to-end method. These separate segments then can be edited together to form a complete production. This method is good for very long and complicated productions but it requires both editing skill and production time. For shorter productions, the prerecorded music and sound effects method is recommended.

RECORDER AND REPRODUCER SETUP

Before beginning production, you should make sure all the recorders and reproducers have calibrated levels. Commonly, a 1000-cycle tone is used to set all the VU (volume-units) meters (both in record and reproduce modes) to 100 percent. The tone serves as a reference point for aligning the different recorders you may be using. Most studios have the tone hard-wired into the control board or the control room patch panel. Other production studios have the tone prerecorded on a cartridge.

SPECIAL EFFECTS

In audio production, there are times when an ordinary sound is not enough to convey the message or the intent of the script. Accordingly, you may enhance or change a sound electronically to produce an entirely different effect.

The five most commonly used special effects are as follows:

- Filtering
- Equalization
- Reverb and echo
- Phasing

All of the audio effects covered in this section are produced electronically using studio equipment (except phasing).

Filtering

A filter is an electronic circuit designed to pass only selected frequencies and to eliminate all others. An audio signal filtering device is often built into the control board or wired into the studio patch panel. Using filters, you can reduce the lows and enhance the highs of a microphone signal to simulate a voice coming from a telephone or radio speaker. Filtering is most commonly used during the recording process.

Equalization

Equalization is similar to, but has more exacting results than, filtering. An equalizer is a piece of equipment that alters the frequency response of an audio signal, allowing for the modification of specific portions of the overall signal. In other words, whereas equalization does not totally eliminate frequencies—it does vary their playback level. You can use an equalizer to match audio originating in-studio with on-location audio by adjusting specific audio frequencies.

Another common use of equalization is to correct acoustical problems that occur at remote recording locations.

Reverb and Echo

The terms *reverb* and *echo* are often used interchangeably, but are two distinctly different sounds. Echo is defined as the repetition of sound. Reverb is the persistence of sound until it fades away and it is usually achieved by using a cartridge machine.

To get either effect, just open up that particular pot (potentiometer) of the recorder while you are recording on that same machine. The more you open the pot, the greater the effect. To achieve the echo effect on a tape machine, you must set the machine function switches to both playback and record. This is

not necessary when using a cartridge machine because it only has a record switch. Of the two effects, reverb can be distorted more easily. Both effects can be overdone to the point that the message cannot be understood. Therefore, you should use these effects with caution.

Phasing

Phasing is that spacey, wavelike sound you sometimes hear on the voice for rock concert promotions. This effect adds depth to the sound and is usually used to enhance the voice. It is achieved when two identical audio sources are played back at slightly different start times.

To get a better idea of what phasing is, try it out for yourself. First, record a piece of copy, and then make an identical copy of it on another tape. Record both copies onto a third tape, starting the first two a split second apart. If you start them too far apart, you will have an echo. If you start them too close together, the phase effect will not be pronounced enough.

Digital audio tape machines and computer software programs have made it much easier to produce and edit audio cuts. With this technology, you can cut and splice segments, taking out errors and pauses, or inserting segments that you have already recorded. By experimenting with the equipment you might even create an audio effect that is unique. Let your creativity guide you.

Do not overuse studio effects; they can become tiring to the ear and may cover the intended message of the production. An advantage of radio is that it lends itself to the audience's imagination better than television does. Through the clever use of studio effects and radio sound, you can exploit this advantage to take your listener on a trip to Hawaii while he never leaves his living room.

ORGANIZATION

Organization is the key to making the most of production time. Think the whole process through before you walk into the studio. This will reduce frustration. If you are not prepared and things do not work the way you want them to, frustration sets in and the production becomes that much more difficult.

QUALITY CONTROL

When completed, the production has made a drastic transformation from a producer's imagination,

to a script, and finally to a recorded tape or cartridge. Throughout this gradual change, certain internal checks were applied to make a high-quality product according to aesthetical and technical standards commonly recognized by broadcasters and the specific requirements of the local station.

Quality control is the responsibility of every broadcaster and will mean the success or failure of the objectives of the production.

PRODUCTION PHASES

The internal checks and balances previously mentioned come during the following three phases of the development of the production:

- Preproduction
- Production
- Postproduction

Preproduction

Preproduction is the gathering of all the supporting elements called for in the script and auditioning specific music and sound effect cuts to make sure they are appropriate. Many times, what the scriptwriter envisioned on paper turns out to be inappropriate in the audio production. The music (tempo, key and melody theme) should convey to the listener a mood that supports and enhances the objective of the production. Your ear is the best judge of whether a piece is aesthetically correct for the production, and it should be obvious if there is a mood mismatch. This is a good time to audition any background music that contains vocals.

There is no absolute rule against using vocal songs as long as it is important to the message and the levels (narration and music) are set correctly. The background music, with or without vocals, is acceptable only if it remains **in the background**. It is easy for the music to end up overpowering the message. Your using vocals for background music means you will have to make a close check on the level balance during the production and postproduction phases.

Check all supportive elements to make sure they meet technical broadcast standards. The script may call for a sound effect that is only available on an old tape that is distorted when played. In that case, find a similar effect on a newer, cleaner tape, computer or CD, or create the effect yourself. If actualities from

other sources are used (interviews, news inserts, etc.), they also must be produced cleanly and be understood easily.

Review the script and note any unfamiliar words or names. Look up the pronunciations of any that may be a problem for you. If another voice is called for, make arrangements for someone else to be in the studio at the appointed production date and time and have copies of the script prepared for him.

Furthermore, before you begin the production phase, know and understand the format requirements for your product. In other words, is the final package to be on audio tape, computer hard drive, or CD? How long will the spot run on-air? What is the timing requirement? When these technical questions have been answered, you are ready to go into the studio.

Production

Once in the studio, make sure all the required equipment is in good working order. Follow the locally established procedures for setting up and checking the audio console and equipment needed for your production. You should erase any production tapes you use. Using tapes that still have audio from other productions can make tape cueing difficult and may lead to the unintentional airing of unwanted audio. You should label all tapes used in the production process so you can easily find the element you need.

Follow the approved script. Unless you are the writer, do not make substantial changes to the content without first checking with the author. There may be a good reason for the script appearing as it does.

Monitor the record and playback levels constantly during the mixing process. When putting several elements together, listen closely in the headphones to the level balance. Remember, do not let supporting sound override primary audio. Check the master tape recording level to make sure its average peaks are between 80 and 100 percent on the recorder VU meter. If you thoroughly complete the preproduction organization, it will be easy for you to follow the script during the production phase.

Postproduction

You should listen to the finished product and make sure the production accomplishes its intended purpose. Listen for quality checks you may have missed in earlier development. Pay particular attention to the audio levels and quality of the final recording. If the

spot or feature is not satisfactory, mix it again and correct the problem. Check to be sure the production meets the allotted time requirement.

When the final product passes all the quality control checks, label it according to local procedure and turn it over to your supervisor.

RADIO CONTROL ROOM EQUIPMENT

LEARNING OBJECTIVE: *Identify the equipment in a radio control room.*

Radio broadcasters find out early in their careers that broadcasting involves more than just announcing. Broadcasters working in the radio medium also must be proficient at operating radio control room equipment. In this section, we will cover the various pieces of equipment that make up a radio control room.

AUDIO CONSOLE

Even though all audio consoles are operated in the same basic manner and perform the same primary functions, their capabilities are not always the same. Differences among consoles are obvious from one model to the next, but even consoles of the same make and model often are locally engineered to perform various additional functions.

Before you operate your console for the first time, take the time to learn its various intricacies. Figure 13-2 shows a typical audio console.

The audio console connects the microphones, cartridge machines, reel-to-reel tape recorders/reproducers, remote lines, CD players and other audio equipment into one system.

In the following text we describe the controls on the audio console shown in figure 13-2:

- **Microphone selector buttons.** There are two identical controls for the operation of microphones on the audio console (channels one and two).
- **CD selector buttons.** Channels three and four control CD players one and two. Because everything is read from left to right, CD one is selected by depressing selector button number one on channel three. Selector button number two on channel four operates CD two.
- **Digital audio tape (DAT) selector buttons.** Tape one is programmed through selector button number one on channel five and tape two through selector button number two on channel six.
- **Cartridge selector buttons.** Three cartridge machines are programmed through channels seven, eight and nine.
- **AFRTS/network selector buttons.** Channel 10 receives audio originating from the AFRTS Broadcast Center (BC) and major radio networks.

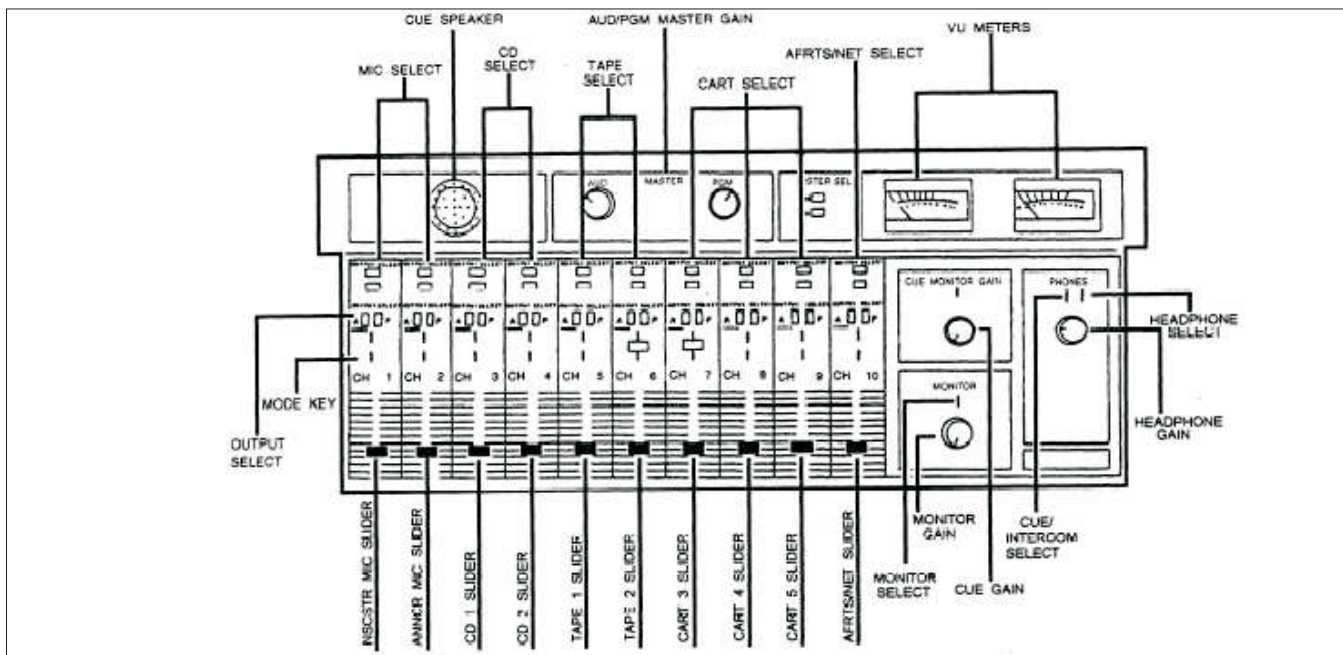

Figure 13-2.—Audio console.

- **Output selector buttons.** All 10 channels on this audio console have the following two output options: audition and program.
- **Mode keys.** This key has three positions. When a sound source is not being used, the key is maintained in the neutral (off) position. Pushing the key up into the audition/program bus places your sound source on the air. Moving the key into the cue position allows you to hear the source only in the studio and not on the air.
- **Cue/intercom selector.** This selector allows you to cue a sound source over the cue speaker or permits broadcasters to communicate between studios.
- **Cue gain control.** This control regulates the volume of the cue speaker.
- **Headphone selector.** This control is used to select the audio source that is heard through the headphones. The three positions are audition, program and cue.
- **Headphone gain control.** The headphone gain control is located immediately below the headphone selector. Set this level to hear your program sound source clearly, but not at a point where sounds within the studio are drowned out.
- **Monitor selector switch.** The monitor selector switch is used to select which audio source is heard on the “air” monitor speakers located in the studio. The three positions are audition, program and air.
- **Monitor gain control.** This control regulates the volume of the monitor speakers.
- **Audition/program master gain controls. DO NOT ADJUST THESE CONTROLS!** They control the output of the entire audio console and are set by the station engineers.
- **VU meters.** The VU meters give the only visual reference to sound loudness. As described previously, the correct meter readings are achieved when average music and voice peaks fall between 80 and 100 percent. Allowing the meter to run constantly in the red, known as running “hot,” can create sound distortion and is never acceptable.

SLIDERS

Sound sources connected to your audio console are controlled by the use of pots, called sliders. The output selected above the sliders gives you the option of listening to the sound source in audition or program mode. Program is used **only** when a sound source is aired. Audition allows you to listen to a sound source to make sure it is properly cued and the appropriate sound levels are set on the VU meter.

AUDIO APE CARTRIDGE, CARTRIDGE MACHINES AND COMPUTER SYSTEMS

You will use audio tape cartridges, cartridge machines and computer software programs (fig. 13-3) for most of the spot announcements of your station.

Figure 13-3. Radio computer software programs.

Cartridges are normally recorded in lengths from 10 seconds to five minutes .

Before you air a spot announcement on cartridge, perform the following steps:

1. Make sure the cartridge is properly seated in the machine.
2. Set the output selector to audition.
3. Start the cartridge and set the output level (using the appropriate slider) on the audition VU meter.
4. Allow the cartridge to play through until it recues.
5. Once the cartridge recues, place the output selector in the program mode. The spot announcement on cartridge is now ready to air.

A digital audio tape machine and digital cart machine are shown in figure 13-4.

CD PLAYER

You will use CD players for production purposes. Commercially, the CD and CD player have replaced records and turntables. This is because CDs are easier to store and their sound quality is superior.

The CD is a 4 3/4-inch plastic platter that is scanned by a laser beam positioned above the disc. Unlike records, CDs do not skip and its 500th play will sound as flawless as its first. However, you should handle a CD only around its edges and store it in its protective case (jewel box). A CD and CD player are shown in figure 13-5.

DIGITAL TAPE RECORDERS/REPRODUCERS

Digital audio tape players and digital cart machines have made producing audio cuts and programs much easier and less time consuming than in past years. Depending on how large your broadcast detachment or SITE radio station is, the more modern radio broadcast equipment will be installed in your radio studios. Not all radio outlets have the latest in broadcast technology, but all outlets do have equipment that allows them to produce quality radio programs, local newscasts and local spot announcements. Mini-disk cart machines, digital audio tape and computers have given radio outlets an unlimited source of audio production materials, capable of a myriad of broadcast techniques.

Figure 13-4.—Digital audio cassette and digicart player.

Figure 13-5.—Compact disc (CD) player.

MICROPHONES

Setting up your studio microphones before airtime is a relatively simple task. Sit down at the console in the same position you will use when producing or working on air. Place the microphone 4 to 6 inches from your mouth at a 45-degree angle. It is possible to set a microphone level by placing the output select in the audition mode and setting the level on the VU meter by using the proper slider. Once you do this, place the output select back into the program mode. Repeat this procedure for the newscaster's microphone.

RADIO CONTROL ROOM HINTS

Exactly how you get the source “on the air” is simply a matter of choice and experience. Each operator develops his own method of preparing for and actually airing a sound source, and each method has its pros and cons that you should take into account.

The following are some radio control room hints for you to consider.

- Be certain the correct source is aired at the specified time.
- Monitor the VU meter while the source is playing and adjust the volume, if necessary, to maintain the proper VU level.
- If you play two or more sources at the same time, make sure the primary source does not drown out the secondary source(s). You can do this by running the primary source at about 80 percent and the secondary source(s) at about 50 percent initially, adjusting for a final overall output of between 80 and 100 percent.
- If the sound source goes off the air unexpectedly and cannot be restored within a reasonable

amount of time (say within 5 seconds), fill the time according to your station's emergency procedures.

- **Practice!** To understand your radio control room equipment fully, you will need hands-on experience. The more time you spend practicing studio operations, the sharper your mechanical skills will be.

EDITING AUDIOTAPE

LEARNING OBJECTIVE: *Identify the method used to edit audiotape.*

One of the main advantages of working with digital audio is that you can edit program material easily. You can remove mistakes and unwanted material from your program to form a cohesive, polished product. The editing process also will allow you to adjust the run time of a program by shortening or lengthening a taped segment. In addition, you may add taped material to another taped program through the editing process.

EDITING PROCESS

The most common method of editing audiotape is for the unwanted material to be cut out. Although this method has been in place since the introduction of magnetic recording tape many years ago, digital audio technology has simplified the process considerably. As mentioned earlier, depending on which broadcast equipment your radio outlet is supplied with, editing your radio product will require very little training.

RADIO PROGRAM MATERIALS

LEARNING OBJECTIVE: *Identify the radio program materials available from AFRTS.*

This section briefly describes the various radio program materials available from AFRTS-BC. It is important for you to know the program materials available from the Broadcast Center since you will rely on them for most of your day-to-day radio programming needs. If you need more detailed information, see the *American Forces Radio and Television Service (AFRTS) Program Materials*, DoD Directive 5120.20-R, Appendix F.

In the mid-1990s, AFRTS moved into the mainstream of modern technology by using compressed video and audio signals that are

transmitted to broadcast outlets around the world via satellite. This technology allows radio outlets to receive as many as 12 different live radio feeds and formats, from hot country and adult contemporary to talk radio and live sports events. These feeds allow program directors to compile their broadcast schedules with a good mix of music formats that support their local live blocks. Depending on the number of radio stations at your command, you will be able to provide your radio audience a wide-range of current music and information, as well as local command information spots and local newscasts.

Navy ships that are deploying receive radio program packages from the Broadcast Center to assist them with their programming. Some ships, however, are capable of receiving the AFRTS satellite feed, which gives the ship the same broadcast capabilities as overseas radio outlets.

In addition, the Navy operates its own Direct-to-Sailor (DTS) satellite system that broadcasts radio, television and information of a more Navywide interest 24 hours a day, 365 days a year.

DTS came into being in 1998 and has proved to be an immediate success throughout the fleet. Navy ships at sea that are capable of receiving DTS, have the benefit of receiving live radio and television feeds, which was simply unheard of a few years ago. This means ships at sea can watch and/or listen to events like the Super Bowl, World Series, the Olympics and major news evolutions as they are happening throughout the world.

HANDLING INCOMING SHIPMENTS

When a shipment of radio program materials arrives at your station, make sure you take the following actions:

- Inspect the exterior of the packages. Make sure the boxes are not torn, ripped, crushed or otherwise damaged.
- Double-check the address to make sure your station is entitled to receive the shipment.
- Carefully open the boxes or containers.
- Locate the packing list and inventory the contents of the packages against the packing list.
- Check each tape or CD label. Make sure that they match the packing list.
- Inspect each item for damage. Look for scratches and defects.
- Note all shortcomings on the packing list.
- Sort tapes and CDs according to the types of units (RP, RU, etc.).
- File the tapes and CDs according to local guidance.

GENERAL HANDLING GUIDELINES

All tapes and CDs must be handled with care. Careless practices, such as leaving CDs on a table without protecting them, result in scratches or chips. A tape left in the production studio unmarked and out of the box is an invitation for someone to erase it. Therefore, tapes and CDs must be cared for according to standard industry techniques and practices.

Cleanliness is paramount. Areas where tapes and CDs are used and stored should be free of dust, high humidity and excessive heat. Keep your hands clean and avoid touching the surfaces of tapes and CDs with your fingers. As mentioned earlier, you should always store CDs in their protective jewel boxes.

CHAPTER 14

TELEVISION

Television is the offspring of three media — the theater, film and radio. Since 1950, television has progressed from a mere novelty, to arguably the most powerful information and entertainment medium.

The technological advancements of television in this short time frame are quite remarkable. Color television sets virtually replaced black-and-white models, cable television eliminated the need for viewers to tune in broadcast channels with “rabbit ear” antennas, and videotape, videotape machines and character generators (CGs) signaled the end of 16mm television film and cumbersome production equipment and methods.

The military services recognized the potential of this new form of communication and started American Forces Television at Limestone Air Force Base, Maine, in 1953. The success of this experimental station convinced DoD officials that overseas television stations were feasible. One year later, the DoD officially recognized the television mission and combined it with American Forces Radio to form the American Forces Radio and Television Service (AFRTS). In 1976, the CNO established the Navy Broadcasting Service (NBS), now the Naval Media Center Broadcasting Department (NMC), to manage AFRTS outlets within the DON.

Most likely, your initial television broadcasting experience will be with an NMC detachment overseas or aboard a ship equipped with a Shipboard Information, Training and Entertainment (SITE) system. For these reasons, you are responsible for knowing the basics of this fascinating but demanding medium.

HOW TELEVISION WORKS

LEARNING OBJECTIVE: *Identify how the television medium works.*

Television is the process of converting reflected light rays from a subject or scene into electrical impulses and reproducing these impulses at a distant receiver.

The television camera picks up reflections of light from the scene, while the microphone picks up sound. The camera changes the light reflections into electrical impulses, and at the same time, the microphone changes the sound into electrical impulses. These impulses are sent to the transmitter or are recorded on videotape.

To be viewed, the signal from the transmitter is received by the viewer’s television set, or the recording is played back — either to the transmitter or directly to a receiver. At the receiver, the picture and sound signals are isolated and sent through separate picture and sound circuits. Electronic components within your television set change these signals back to video on the cathode-ray picture tube and audio on the television speaker.

THE TELEVISION CAMERA

LEARNING OBJECTIVE: *Recognize the basic operation, electronic characteristics and main types of television cameras.*

The television camera is the heart of the television system. It records the varying amounts of light reflected from objects in the televised scene. This amount of light varies according to the lighting, color or shade of the object.

Figure 14-1 shows a banner with the word *NAVY* printed in black on a white background. The border around the banner is gray. When light hits the banner, it reflects from the three different shades in different amounts. The white background reflects the most light, the gray reflects less, and the word *NAVY* reflects very little light. From this you can see that a scene made up of different shades or colors reflects different amounts of light. The television camera takes these various levels of light reflection and changes them into electrical impulses of varying strength.

A television camera is optically similar to a movie camera, except it does not use film. Instead, light reflections from the scene are focused by a lens and pass through the face of the photoelectric transducer (also called a pickup tube) of the camera. The pickup tube does the job of film in a camera. Its surface is

Figure 14-1.—The various amounts of light seen by the television camera.

coated with thousands of tiny globules of silver mixed with other chemical elements. This coating is photosensitive, which means it gives off electrons when exposed to light. Light from the scene covers the entire surface of the pickup tube and electrons are forced off its rear surface. The number of electrons forced off any part of the pickup tube is determined by the amount of light that strikes this part.

In figure 14-1, the Navy banner causes the pickup tube to give off electrons corresponding to the amount of light reflected from various parts of the banner.

At the present time there is no practical method for transmitting a complete video picture instantaneously as a whole unit. Therefore, in television, the picture is broken into tiny units called elements, which are transmitted individually in sequence. The elements are so small that the human eye cannot distinguish one from the other in the complete picture. The process of registering all the elements of a video picture in sequence is called scanning. During the scanning process, the television camera “encodes” the elements; then the television receiver is used to “decode” them in

the proper order to recreate the original image (fig. 14-2).

ELECTRONIC CHARACTERISTICS

In this section, we examine the following electronic characteristics of a television camera:

- Operating light level
- Video noise

Operating Light Level

You need a certain amount of light in order for the pickup tube of the camera to perform its function. Although there are several ways to measure light, the footcandle is one of the more common units of measurement.

Whatever term is used, make sure your light-measuring device is in the same language as the manual for your camera. For example, if the manual calls for a minimum of 100 footcandles of light, you will need a light meter that reads in footcandles.

Some cameras have a way to give you more light when you need it. The dB gain switch (fig. 14-3),

Figure 14-2.—The scanning process.

Figure 14-3.—Television camera dB gain switch.

usually located on the back of the camera, has two positions — 6dB and 12dB. For every 6dB of gain, the camera output signal doubles in amplitude to increase the video level effectively. That means the 6dB setting doubles signal strength and the 12dB setting is four times more than the 6dB gain.

Video Noise

Video noise increases in proportion to the video gain previously described. Even the best cameras will deliver “noisy” pictures under low-light levels. A noisy picture has a great amount of snow, or white vibrating spots, in the picture. This occurs when the

video signals produced by the pickup tube are not strong enough to override the electronic interference the system usually generates. At 12dB gain, the system is generating more electronic interference — and more video noise.

Having covered the basic operation and electronic characteristics of a video camera, we will now examine the types of video cameras you will work with at NMC broadcast detachments.

STUDIO CAMERA

The studio camera (fig. 14-4) is the backbone of the television industry. It is mounted on a dolly pedestal so the camera operator may wheel it to different locations with relative ease during shot changes.

Television technicians monitor and adjust the video levels of the studio camera with the camera control unit (CCU), usually located in the control room. The CCU consists of a waveform monitor (an oscilloscope that displays a video signal graphically), television monitor and shading control.

Studio cameras are expensive, ranging in price from under \$5,000 to more than \$100,000. However, the more expensive cameras deliver high-quality images in a variety of production conditions.

ENG CAMERA

The electronic news gathering (ENG) video camera replaced 16mm motion-picture film for television news in the mid-1970s. Today’s ENG cameras are automated and fully operational within a

Figure 14-4.—Studio camera.

few seconds after they are switched on. You can make adjustments to extreme production situations quickly and easily.

Most ENG cameras weigh between six and 20 pounds, depending on the number of pickup tubes inside the camera. They are powered by batteries, but you may also run them from AC current using an adapter. An ENG camera is shown in figure 14-5.

CONVERTIBLE CAMERA

Some of the more expensive ENG cameras may be converted from an ENG format to a studio camera head with a large viewfinder and advanced zoom lens. In terms of practicality, the convertible camera is tough to beat because you can use the same camera for two distinct applications. For instance, you can use a convertible camera to cover the 11 a.m. ribbon-cutting ceremony at the new Navy Commissary, then connect it to a CCU in the control room for the evening news six hours later. Furthermore, the convertible camera is invaluable for remote productions requiring several cameras, such as sporting and entertainment events. Convertible cameras are shown in figure 14-6.

CAMCORDER

Camcorders are the camera of choice for ENG work. The standard camcorder in the broadcast industry today is a betacam, which uses a fast speed beta format tape and produces excellent video pictures. (See fig. 14-7.)

Another popular video format is Hi-8. This format has several advantages. First, the cameras are small,

compact and easy to carry. The video is not the same quality as beta, but is good enough to edit and use on the air. Hi-8 cameras are also less expensive; sometimes thousands of dollars cheaper than larger camcorders. Most broadcast detachments are equipped with both betacam and Hi-8 cameras. If the production you are shooting affords you plenty of time to shoot the video you require, you should normally use a betacam. When time constraints are imposed, or if you need to capture video in a hurry, Hi-8 or VHS format is the best bet.

Most television editing systems can be set up to use several different video formats, including beta, VHS and Hi-8.

TELEVISION CAMERA OPTICS

LEARNING OBJECTIVE: *Identify the optics of a television camera.*

You were introduced to the functions of camera lenses in chapter 11. The lenses and the associated optics for television cameras (save viewfinder) operate in the same manner as still photography, but we will cover them briefly as they apply to the television medium.

VIEWFINDER

The viewfinder on an ENG camera is a relatively small television screen (1.5 inches in diameter), while a studio camera viewfinder is larger (3 to 9 inches in diameter). They both produce high resolution black-and-white images. The television screen on an

Figure 14-5.—Electronic news gathering (ENG) camera.

Figure 14-6.—Convertible cameras.

ENG camera is shielded from outside reflections by a flexible rubber eyepiece that adjusts to the operator's eye. In that rubber eyepiece, there is an adjustable lens for you to focus since the eye is placed within an inch or two of the screen. The studio viewfinder uses a hood to

shade the television screen from overhead studio lights.

Within the ENG camera viewfinder, there are a number of control lights or displays that indicate the status of certain camera functions. Most viewfinders

Figure 14-7.—Camcorder.

automatically display information on tape status, battery condition, tally/record light and low-light level indicator. The viewfinders display, on command, color bars, patterns, white/black balance setup cursor and camera registration. All camera viewfinders are black-and-white.

In some camera models you may use the viewfinder as a playback monitor for the VCR. The advantage of this feature is that you do not need additional equipment to set up the camera. However, some video camera manufacturers are discontinuing this feature because today's cameras are more reliable and recorders have indicators to let you know when you are recording.

LENS

The lens selects a certain field of view and produces a small, clear optical image of this view. The lens and certain attachments are sometimes called the external optical system.

When you work with video camera lenses, you concern yourself with the following four areas:

- Focal length
- Focus
- F-stop
- Depth of field

Focal Length

As you learned in chapter 11, focal length is the distance from the optical center of the lens (which is

not always its physical center) to the point where the image, as seen by the lens, is in focus.

Portable television cameras have a zoom, or variable focal-length lens (fig. 14-8), that allows you to select fields of view at different distances from the camera without moving the camera. It allows you to change the focal length of the lens from long to short or from short to long in one continuous operation. A complicated series of lenses interact to keep the object in focus at all times during the zooming process. "Zooming in" is the gradual changing of the lens from a wide-angle lens to a narrow-angle lens. On the television screen, a zoom in appears as though the camera is moving smoothly toward the object. "Zooming out" is the changing of the lens from a close-up to a distant shot and it will appear that the camera is moving away.

The degree to which you can change the focal length of a zoom lens is the zoom range of your lens. The range is often given in a ratio, such as a 10:1 zoom range. This means you can increase your focal length 10 times. Some cameras have a "times two function," which allows you to double the focal length at any point in the zoom, thus making the maximum 20:1 for the above example.

You can control the speed of your zoom either manually or by using a zoom servo. These features are covered in the following text.

MANUAL ZOOM CONTROL.—The manual zoom control on ENG cameras is a small rod extending from the zoom ring. To zoom in or out, turn the zoom rod clockwise or counterclockwise. It takes some skill

Figure 14-8.—Zoom lens.

and practice to accomplish smooth zooms with the manual control.

ZOOM SERVO.—A zoom servo is nothing more than a small motor controlled by a lever. The distance the lever is depressed determines the speed of the zoom — typically from 2.5 to 20 seconds. The lever is called the zoom selection or T/W switch — T stands for telephoto and W for wide angle.

There are several advantages to the zoom servo system. Zooms are steady and smooth, especially during slow zooms. The zoom control is easy to operate and allows you to concentrate more on picture composition and focusing. The zoom servo also frees the left hand to operate the manual focus and aperture controls.

You must be aware of two disadvantages of the zoom servo. Although relatively quiet, some zoom servo motors emit a humming noise that is picked up by the camera-mounted microphone. Additionally, the motor uses power provided by the camera battery.

MANUAL FOCUS CONTROL.—The focus control is usually a rubber-covered ring on the zoom lens. To operate it, you rotate the focus ring either clockwise or counterclockwise while looking in the viewfinder to determine if the picture is in focus.

Focus

Two methods of setting the focus on a zoom lens are used. One, called **zoom focus**, is done by zooming all the way in and setting the focus, then zooming out to the desired focal length. Once this is done, everything in the depth of field will remain in focus, including the object focused on, provided the distance between it and the camera does not change.

Another focusing method is called **rack focus**. This is nothing more than your setting the focus on something in the field of view. When you do this, only that object and other objects at the same distance will remain in focus as long as the distance between them and the camera does not change.

You should rack focus when there is not enough time to zoom focus. However, there are times when the effects of a rack focus are desirable, such as when the viewer's attention is directed toward something in the foreground and you want to lead him to another object. You can do this by changing the focus to bring the other object into sharp focus while the first object goes out of focus.

f/Stop

As noted earlier, the camera pickup tube will operate properly only within a certain range of light intensity. If too much or too little light falls on the pickup tube, the picture quality will suffer.

Since you will use the camera both indoors and outdoors, you must compensate for extreme differences in light levels. The lens diaphragm, or iris, is used to control the amount of light that enters the lens and the camera by enlarging or reducing the aperture. The f/stops indicate the size of the lens (diaphragm) opening. The lower the f/stop number, the wider the lens opening. When you zoom in, the lens will require more light, a wider opening and a lower f/stop number.

Most television cameras have an automatic iris that allows you to devote your attention to other important aspects of videography, such as framing and composition. You will, however, have to select the proper filter setting for the scene you are shooting. Although the automatic iris seems ideal for ENG assignments, it does not always work to your advantage. With fairly even illumination, the auto iris closes down when it sees an extremely bright area in a scene or opens up when it senses a large, dark area. You can avoid this by switching to the manual iris control.

Depth of Field

It is important for you to know that f/stops do more than just determine the amount of light entering the camera. They also affect the depth of field.

As in still photography, a large diaphragm opening (small f/stop number) decreases the depth of field, and a small diaphragm opening (large f/stop number) increases it. The same rules apply when you move the camera. A great depth of field makes it easy for you to keep the subject in focus while moving short distances, whereas a shallow depth of field makes it impossible for you to move without getting the subject out of focus.

THE TELEVISION STUDIO PRODUCTION TEAM

LEARNING OBJECTIVE: *Recognize the members of a television studio production team.*

A television production, such as the one shown in figure 14-9, relies on the expertise of several

Figure 14-9.—The talent, camera operator and floor manager on the set of Navy-Marine Corps News.

individuals who do a myriad of jobs. These jobs are interdependent and must be coordinated to perfection.

As a member of a television studio production team, (fig. 14-10) you will be called upon to function in any one of the following positions:

- Talent
- Camera operator
- Floor manager
- Audio switcher
- Graphics operator
- Video switcher
- Director

TALENT

The television studio production centers around a performer of some sort, whether it be the CO explaining a change in base policy on captain's call or a colleague delivering the evening news. In television parlance, the performer is known as the **talent**. An array of support people assists the talent, including those who handle copy, wardrobe and makeup. The talent receives instructions from the director through the floor manager.

CAMERA OPERATOR

The images that appear on the television set are first determined by how and what the camera sees. Images from several cameras may be available for the

Figure 14-10.—Video graphics add a professional touch to television productions and news stories.

director and video switcher to use or blend to produce the transmitted picture. Unlike recorded videotape, the editing of a live studio production is accomplished as the picture is transmitted. Thus the television camera is the most important single television production element. All other elements and techniques are geared to the physical and electronic characteristics of the camera. Lighting, scenery, audio, writing and directing all depend, more or less, on the potential of the camera.

In most television studio productions, there are several cameras operating at the same time. As a camera operator it is your responsibility to make sure you can operate your camera efficiently. You can only be efficient when you are completely familiar with your camera and use practical television camera-operating techniques.

During a production, you wear a headset that gives you direct communication with the director. The director tells you when your shot is about to be used and when it is being used live. Even when your shot is not live, you should attempt to keep a shot that the director may find useful to the program. This will allow him to use that shot for coverage if something goes wrong with another shot or camera.

You may receive instructions from the director to move the camera, either to a new angle or to a new position on the studio floor. It is essential to a successful television production that all camera

movements be carried out correctly, quickly, quietly and smoothly. The director relies heavily on the conduct of the television camera operators, and his job is easier when you respond to his commands not only quickly but accurately. This is particularly important during unscripted programs. (Television shooting techniques, including specific camera movements, are covered later in this chapter.)

FLOOR MANAGER

The floor manager stays in the television studio during a production. Through a headset system he is in direct, two-way communication with the director in the control room. The talent normally is not able to use a headset and cannot receive instructions directly from the director. It is the prime responsibility of the floor manager to act as a liaison between the talent and the director.

Since it is not practical for him to instruct the talent orally during a production, the floor manager stands or kneels next to the camera that the talent should speak to and uses a system of hand signals to relay the director's instructions. Although any hand signal system understood by both the floor manager and the talent will work, we recommend you use the universally accepted system shown in figure 14-11.

Figure 14-11.—Floor manager's hand signals.

The basic hand signals that the floor manager and talent must understand are listed in the following text.

- Stand by. For the hand signal to “stand by,” the floor manager raises his hand and arm at the beginning of the show or following a spot break.
- Cue. For the hand signal to “start talking” or “begin action,” the floor manager raises his hand and points to the talent.
- Cut. For the hand signal to “cease talking” or “stop action,” the floor manager draws his hand across his throat in a slashing motion.

- **Stretch.** For the hand signal to “stretch it” or “slow down,” the floor manager pulls his hands apart as if stretching a rubber band. Longer amounts of time are indicated when the floor manager places his hands farther apart at the end of the stretching motion; shorter time amounts are indicated when the floor manager places his hands closer together.
- **Speed up.** For the hand signal to “talk faster,” the floor manager rotates his arm and hand clockwise in a circle above his head. The speed of the rotations are related to the urgency of time.
- **OK.** For the hand signal that “everything is fine,” the floor manager makes a circle with his thumb and forefinger.
- **30 seconds to go.** For the hand signal that there are 30 seconds remaining in the show/segment, the floor manager forms the letter *T* with both hands.
- **15 seconds to go/wrap it up.** For the hand signal that there are 15 seconds remaining in the show/segment and the talent should wrap up what he is doing, the floor manager creates a grabbing motion with his hand that results in a fist.
- **Speak more softly.** For the hand signal to “speak more softly,” the floor manager raises the palm of his hand to his mouth.
- **Speak up.** For the hand signal to “speak up,” the floor manager cups his ear with his hand.
- **Speak or look at this camera.** For the hand signal to “speak or look at this camera,” the floor manager points to the on-air camera with his hand. A waving motion from one camera to another alerts the talent that the director is switching the shot to another on-air camera.

Be precise and deliberate when you deliver hand signals. Do not wave your arms in the air frantically — this will only confuse and irritate the talent.

During a television production, the studio floor is usually a maze of lighting and camera cables that can hinder the movement of the cameras and also be a safety hazard. The floor manager must make sure these cables are stored or positioned safely. Furthermore, he should find out from the camera operator and director how much camera movement is expected.

Once a production is under way, any number of problems may develop on the studio floor. Cameras may refuse to move or the talent may develop giggling fits. In normal circumstances, the only way the director can find out about these problems is through the floor manager. Therefore, another responsibility of the floor manager is to keep the director informed of any developing situations on the studio floor that may affect the program.

AUDIO SWITCHER

The audio switcher is responsible for the smooth operation of the television audio mixing console. He must be able to respond quickly and correctly to the commands of the director.

The television audio mixing console is usually located next to the video switcher in the main television control room. The console itself has all the sound inputs fed into it including microphones from the studio floor, cart machines, CD players, video tape players and so forth. The audio switcher has absolute control over these inputs and must balance them so that they are at a compatible level.

VIDEO SWITCHER

Although the camera operator frames the shot and the director calls for it, the video switcher (fig. 14-12) is ultimately accountable for the picture that is recorded or broadcast. The video switcher is responsible for the smooth operation of the video-mixing console and the special effects bank. He directly controls what the audience sees. A mistake on his part cannot be covered up by the director.

The video switcher sits at the video-mixing console throughout the production and is completely responsible for its smooth operation. He must be able to operate the console efficiently and respond quickly and correctly to the commands of the director. The video switcher can only achieve such efficiency by having a thorough knowledge of the console equipment and by constantly practicing mixing techniques. In addition, the video switcher must know how to apply the various special effects available to him and operate them smoothly.

DIRECTOR

The television studio production crew is a team, with everyone in the team working together toward one common goal — the successful airing of a production.

Figure 14-12.—Video switcher.

Although each member of the team is responsible for the correct and efficient operation of his particular task, there has to be someone in charge — someone with an overall view of the situation and the way the various tasks are accomplished. This person is the director.

The director is totally responsible for the production. He is able to give instructions to every member of the crew, either directly, or in the case of the talent, indirectly. These instructions must be clear and concise — garbled instructions are worse than no instructions at all.

In a scripted production, only the talent *needs* a script, but it is the director's responsibility to be completely familiar with it so he may devote more of his attention to the actual production and less time wondering what the talent is going to do next.

It is also the director's responsibility to be aware of the functions of each member of his crew and their equipment. There is probably nothing worse and more frustrating for a production crew than to work with a director who sets impossible tasks for his crew because he is unaware of the functions and limitations of his people and their equipment.

During a studio production, the director gives commands to the camera operators and the audio, video and graphics switchers. These commands are covered in the following text.

Camera Commands

The director issues commands to the camera operators more than any other production team member to accomplish the following tasks:

- Set up shots
- Refine the framing and composition of a shot
- Direct the movement of a camera while the shot is on the air

When you serve as a director, you should remember the following guidelines:

1. Give a “ready” or “standby” cue whenever possible. Your doing so tells the camera operator to hold a particular shot and that airing is eminent. Additionally, it is a good practice that you give a “ready” command just before a camera movement. For instance, if the talent is seated and is scheduled to get up and move to the left, you would say, “Camera 3, *ready* to pan right with the talent.”

2. Identify each camera by number. You will know each camera operator by name, but you should issue camera commands using the appropriate camera number.

3. Begin a command with the camera number. Do not say, “Ready to pan right with the talent, Camera 3.”

4. Be specific when issuing commands. For example, the command “Camera 1, zoom out” is too vague for production work. Instead, you should say: “Camera 1, zoom out for a bust shot.”

Switcher Commands

The director should follow the same basic guidelines for camera commands when issuing commands to the video, graphics and audio switchers. In some situations, the director will give switcher commands while actually performing the switching functions himself. This is done primarily to alert team members of video, graphics and audio transitions.

Try to economize your words when you issue switcher commands. For instance, instead of saying, “Ready to cut to Camera 2 ... Cut to Camera 2,” say “Ready to take 2 ... take 2.” Your using fewer words takes less time and cuts down on the possibility of confusing team members.

In addition, you should give commands to the video switcher *last*. This is because the video switcher is normally positioned close to the director and needs less time to respond to a command than camera operators or the floor manager. Give your commands in this order:

1. Audio switcher
2. Talent
3. Graphics switcher
4. Video switcher

TELEVISION VISUALS

LEARNING OBJECTIVE: *Recognize the technical requirements and main types of television visuals.*

As a television broadcaster, you must be able to think visually in order to make the most of the television medium. In some cases, visuals can tell the entire story by themselves and should be an integral part of a production instead of an afterthought. You may have heard the cliché, “One picture is worth a

thousand words.” This is true because effective visuals will help you tell the story with more clarity. A viewer’s imagination can actually provide the “soundtrack,” sometimes enhanced by narration (used sparingly) and television dialogue.

The term *visuals* may be broken down into the following three subgroups:

- Graphics (maps, charts, diagrams, illustrations, printed IDs, outlines and summaries and CG information)
- Photographic techniques (videos, slides and still photographs)
- Television backdrops, props, scenery and subject/talent visual information not included in the first two categories

TECHNICAL REQUIREMENTS

Before you plan or use any type of television visual, you must be aware of the technical limitations and guidelines involved. Even if you do not actually design or prepare the visuals, you must be able to guide your artist and understand the limitations of visuals.

It is important for you to understand how visuals must be tailored for television before producing or selecting them. For example, a novice television broadcaster may see a random visual he likes and tries to use it immediately, while a seasoned veteran will base his decision on more scientific guidelines and will not rely on first impressions.

Any producer of television programs learns quickly that he needs a “working knowledge” of many contributory fields. One of these is graphic arts. All television shows use graphic materials — titles, name keys, slides, photographs, illustrations, charts and maps — just to name a few. Graphic materials greatly enhance news and feature productions, spot announcements and virtually all types of television programs. Keep in mind that, in television, it is important for you to present information visually as often as possible since people remember visual information longer than the spoken word. Without visuals, you lose the force of this powerful medium.

Whether written, pictorial, diagrammatic or sheer design, visuals have a place in almost every television production. In preparing visuals for television, you should pay close attention to the aspect ratio, scanning area, essential area, border area and the size of the visuals.

Aspect Ratio

The aspect ratio of any television screen, regardless of its physical size, is 3:4. This means the television screen is divided into three units high and four units wide. The visual elements should be kept in a format size that will complement either 6:8 or 9:12. These aspect ratios will help you keep the materials and objects within the 3:4 aspect ratio format shown in figure 14-13. A television visual prepared within this aspect ratio will be seen in its entirety on the television screen. Conversely, think about what would happen if you were to shoot a vertical photograph without the proper aspect ratio. The photograph would lose a major portion of its information from either the top or bottom, or its sides and it would look visually poor on the television screen.

Scanning Area

The total area seen by the camera is called the scanning area. This image is transmitted fully, but the outer edges and the corners usually do not appear on the home television set because of the shape of the picture tube. A properly aligned television receiver will display all scanned information at the top and bottom center of the picture, but will crop corners because of the nonsquare corners of the picture tube.

The common mistake many new television broadcasters make is allowing too much headroom at the top of the picture. Remember: the home receiver sees everything at the top center, so do not overcompensate the same way you do for edge and corner cropping.

Figure 14-13.—Television aspect ratio.

Essential Area

The portion of the picture that reaches the viewer must include all of the important information — this is known as the essential area. All visuals have a scanning area and an essential area. The scanning area is the entire picture from top to bottom and from side to side. The essential area is the meat of the picture — the main information within that picture area. Both the scanning and essential areas of a picture are shown in figure 14-14.

Remember to use the scanning area! The total scanning area is visible on most television sets, but there is a 10-percent loss on others (fig. 14-15). Therefore, keep all pertinent information within the essential or “safe” area. This is especially critical when you use words.

TYPES OF VISUALS

The types and uses of visuals are limited only by your imagination. Visuals come in various forms, each having a name that makes it easily identifiable to production and artwork staff members.

The following is a list of the major types of television visuals and graphics:

- News/program pictures and slides
- Graphic information scrolls
- Sports graphics and score charts
- Super/key card
- Chroma key card

Figure 14-14.—Scanning and essential areas of a television picture.

- Maps and charts
- Character generator
- Computer graphics

Character Generator

Television has changed dramatically over the last 20 years - especially when it comes to visuals and graphics. In the early days of television, title cards and photographs were placed on an easel in the studio and filmed by the studio camera. The director would either take the shot on-air, or superimpose the shot over another one.

Today, nearly every television studio has a computer graphics character generator (CG) (fig. 14-16) that performs a myriad of tasks that help make your production a professional product. Name keys, titles, graphics and photographs, pie charts and bar graphs and special effects can be composed on the CG and stored on the computer hard drive for air at a later date. These files can easily be recalled and placed on-air during a live production, and greatly enhance the final product.

Although the CG is a timely means to display information, you should not rule out the use of other graphic support material.

Computer Graphics

Computer graphics, the newest elements of the television medium have all but replaced 35mm slides for television work. It starts with an electronic picture recorded on videotape. The computer operator converts the picture into a digital code format and stores it either on the hard disk drive or a floppy drive. When the image is needed, a graphic artist retrieves it

and converts it into an electronic picture. Now he may paint or draw a picture using an electronic pen and palette. The graphic artist can add or delete information and change the colors of the picture and letters at will while “on-the-air.” Some advanced computer graphic systems have a wide range of colors and can produce detailed animation.

A computer graphic system is shown in figure 14-17.

Plain Title Card

The plain title card has printed lettering (without any pictorial background), such as the title of the show, the name of the performers and producer and so forth. Rich, deep color backgrounds with light lettering makes reading easy.

Super/Key Card

During the showing of a super/key card, the card lettering is superimposed electronically over another background (or over another picture) from either another camera or from a film chain camera. This technique is an accepted form for placing the name of the subject on the air while the subject is talking. Use only simple, bold letters and try to restrict the amount of information on the super/key card. Normally you should avoid white lettering on a black background, because the contrast between the two is too great. Nonetheless, in this case, the lettering must be white and the background black.

Use caution when you plan the super/key card. You must consider how two camera shots will look as one picture. In addition, you should place lettering in the lower third of the card and center the card on the picture. This is done so you will not obstruct the background or the main action.

PREPARING TELEVISION VISUALS

LEARNING OBJECTIVE: *Identify the techniques used to prepare television visuals.*

Regardless of the purpose or format of your television visual, you must consider the following basic aesthetic elements:

- Simplicity
- Contrast
- Balance and composition
- Lettering

Figure 14-15.—Transmission loss.

SIMPLICITY

The old adage, “Keep It Short and Simple” (KISS), certainly applies when you create television visuals. Your visual should be uncomplicated and easily recognized. Do not make the viewer work too hard to understand what he is seeing. For example, viewers normally will ignore a visual with too much lettering. Additionally, try to keep colors to a minimum.

All copy or lettering must be readable. Fancy fonts may look good on paper, but they might not permit the viewer to understand what you are trying to convey.

Sizing of the subject in the picture also is important. Keep the primary subject somewhat large within the picture that you are framing. Do not make the viewer strain to read or see the subject. A good subject size is about one-half inch in height on a 19-inch monitor.

CONTRAST

High definition, or contrast quality, is important for reproduction over a television system. Contrast in visuals should be sharp but not excessive. Avoid large areas of white. The pickup tube(s) of the camera will transmit glitter and flair when you shoot high-intensity reflected light, especially during camera movement. This also may introduce audio noise into the television picture.

The human eye can identify about 100 different shades of gray. The television camera clearly identifies only about 10 shades. Since the brightest area can be no more than 20 times as bright as the darkest area, you must be careful when using pictures and visuals that have high contrast.

You also should consider how color will appear on a black-and-white (monochrome) television set. Color material will appear as shades of gray on a monochrome television set and must be used according to its gray scale value. The best way to test colors is to check them with a color television camera and monitor. You will find that brown, purple, dark blue and black appear black on a monochrome television; red, medium blue and medium green appear dark gray; light blue, chartreuse, gold and orange appear light gray; and pastels, bright yellow, light gray and tan appear almost white.

Even a color television system acts as a filter — it only sees a portion of the hue (color) and saturation (color strength) that the human eye can see. Most color cameras have trouble with the colors red and orange. Saturated colors cause excessive video noise or color stretching over the entire screen. Stripes or color banding also may show up as color vibrations, thus disrupting the picture. Stay with basic, solid colors — primarily blues and greens — and avoid supersaturated reds and oranges.

Studies have revealed that color may influence our judgments of size, weight and temperature and even affects our psychological state of mind. Colors are viewed as “high energy” or “low energy.” Cool colors are considered low energy; warm colors are termed “high energy.” Make sure you avoid using two colors that have the same value on the gray scale.

BALANCE AND COMPOSITION

Balance and composition are also important factors when you design television visuals. For full screen visuals, make sure the design is balanced and

Figure 14-16.—Character generator (CG).

Figure 14-17.—Computer graphic system.

aesthetically pleasing to the viewer. Try to visualize the final, on-air picture before you use it in a production.

LETTERING

The viewer will not see letters too small or too thin. A general rule of thumb is not to use letters smaller than 15 to 20 percent of the essential area. If the visual is too busy or includes too much material, it will probably distract your audience. Five or six lines of 15 to 20 characters is considered the most a viewer can handle at one time. This is particularly important when you are composing character generator pages for your local newscast, television production or a command community bulletin board channel.

TELEVISION MICROPHONES

LEARNING OBJECTIVE: *Recognize the types of microphones used in television productions.*

Sound plays a vital role in the television communication process. Most human intelligence is transmitted through sound; therefore, good quality sound is an important part of television. However, good quality sound is rather difficult to achieve at times because sound sources may be in motion, talent may speak to the camera and not into the microphone and microphones must sometimes be hidden from the view of the camera. To help solve these audio problems, you

should have a basic understanding of television microphones.

Microphones are usually classified according to the way they pick up sound, also known as their polar pattern. Sound in physical terms is the vibration of air particles or small fluctuations of air pressure that spread like waves from a source of sound. Human ears respond to this change in pressure within a sound field. Similar to a human ear, microphones respond to the change in air pressure created by sound waves and convert the fluctuations of pressure into electrical current.

POLAR PATTERNS

The pickup, or polar pattern of a microphone, is the shape of the area around it where it picks up sounds with maximum fidelity and volume. Nearly all microphones can pick up sounds from areas outside the ideal pattern, but their quality is not as good. For best results, the sound source should be within the pickup pattern, generating enough volume to allow the audio switcher to keep the volume control at a minimal level.

Microphones are classified according to the following three basic polar patterns:

- Unidirectional
- Omnidirectional
- Bidirectional

Unidirectional

The unidirectional microphone picks up sound from only one direction. Because of this characteristic, the unidirectional microphone is used most frequently for television work. It is used by aiming it in the direction of the sound source being recorded. One advantage to the unidirectional microphone is its ability to reject unwanted sounds at the side and rear of the direction the microphone is aimed.

Omnidirectional

The omnidirectional (or nondirectional) microphone is live in all directions. This type of microphone has sensitivity characteristics in which sound is picked up in a 360-degree radius. The use of this microphone in television production is limited; however, in certain situations, you may use it to create a specific sound presence. One example is recording crowd noise for a sports production.

Bidirectional

As the name implies, the bidirectional microphone picks up sound in two directions. This type of microphone is used primarily in the broadcast or recording studio. It is also used for critical sound reinforcement applications, in which, front and rear pickup and greatly reduced side pickup is desirable.

The bidirectional microphone is ideal for such applications as “across the table” interviews or dialogue recording under studio conditions.

The polar patterns of all three microphones are shown in figure 14-18.

MOBILE MICROPHONES

During your tour as a television broadcaster, you will use the following four basic types of mobile microphones:

- Boom
- Hand
- Lavalier
- Wireless

Boom

The most flexible mobile microphone is one that is attached to a microphone boom. A boom, in its simplest form, is a hand-held pole to which a unidirectional microphone is attached. It permits quick and smooth movement of the microphone from spot to spot anywhere on the set. Most booms have a telescoping feature that allows the operator to extend or retract the microphone. Some booms have controls at the end so the operator can rotate the microphone for directional sound pickup.

Figure 14-18.—Microphone polar patterns.

Another advantage of the boom is its mobility on the set. The boom operator can move the entire boom assembly from location to location and follow sound sources without an interruption to sound pickup. The giraffe boom (fig. 14-19) is suited perfectly for this task.

As a television boom operator, your primary responsibility is to keep the microphone as close to the sound source as possible without getting the microphone or its shadow in the picture. This requires coordination and anticipation. You must keep the microphone in front of the sound source, listen to the director's signals, watch camera movements, be aware of what lenses are in use, avoid undesirable boom shadows and anticipate the talent's movement — all at the same time.

Hand

The hand microphone (fig. 14-20) is used for many television productions, especially ENG shoots. A hand microphone is seen on camera, and therefore, it

can be held very close to the sound source. It is especially useful amidst noisy surroundings, such as the flight line or the machine shop aboard ship. In such cases, good audio pickup is still achieved by holding a unidirectional microphone very close to whomever is speaking. A hand microphone is valuable in audience participation programs, such as Navy Relief and Combined Federal Campaign telethons.

Lavalier

During reporter standups, newscasts, interviews and similar production applications, the lavalier microphone (fig. 14-21) is more appropriate than the use of a hand microphone. Lavalier microphones are small and unobtrusive. They are normally taped or clipped to an article of clothing on the talent's chest and are ideal when microphone concealment, individual mobility or the free use of hands is required.

Although concealment is an attractive option of the lavalier microphone, you should not place it entirely under clothing. Clothing acts as a filter and any sound

Figure 14-19.—Giraffe boom.

Figure 14-20.—Hand microphone.

Figure 14-22.—Dual redundancy lavalier microphones.

Figure 14-21.—Lavalier microphone.

that penetrates the “filter” will be muffled when reproduced. Clothing rubbing against the microphone also can create crackling noises.

Some lavalier microphones are termed *dual redundancy*, because there are actually two lavalieres hooked to the same clip (fig. 14-22). Only one microphone is live, but the other serves as a backup in case the primary microphone fails. For this reason, you should not connect both microphones to the same audio slider in the audio control room.

Wireless

The wireless microphone, as its name implies works without cables. It is a standard lavalier microphone connected to a battery-powered radio transmitter. The talent may clip the transmitter to his belt or conceal it under an article of clothing. A small antenna connected to the transmitter sends the audio signal on an FM frequency to the receiver in the audio control room. The signal is then fed to the audio switcher, who controls the input like any other sound source.

Be careful when you use wireless microphones because they may deliver unwanted audio from radio frequencies (RF) in the area, so exercise caution when you use them. A wireless microphone receiver and transmitter are shown in figure 14-23.

STATIONARY MICROPHONES

In addition to the mobile microphone group, you will become familiar with the following four stationary microphones:

- Desk
- Stand
- Hanging
- Hidden

Figure 14-23.—Wireless microphone receiver and transmitter.

Figure 14-24.—Desk microphone.

Desk

Desk microphones (fig. 14-24) are widely used at public hearings, panel discussions and other productions where the talent is working from behind a desk or lectern. Any microphone can be used as a desk microphone, as long as you attach it to a suitable stand.

Since the talent is heard and seen in television, the placement of the desk microphone is influenced by the camera. If the microphone is placed directly in front of the talent, it may obstruct his face. Further, sound

pickup will be influenced when the talent turns his head.

A good starting point for placing the desk microphone is about one and one-half feet from the talent and pointed at his collarbone, as shown in figure 14-25. If the talent turns his head to look at the television monitor or another talent, try to locate the microphone somewhat to that side.

The actual number of desk microphones needed and their placement depends on the quality of the sound produced. If one desk microphone will suffice, then use just one.

Figure 14-25.—Desk microphone placement.

You should conceal the cables of desk microphones. If a particular desk or table is used almost exclusively with a desk microphone, you can drill a hole into its top and drop the cable to the floor.

Stand

Stand microphones are used when the sound source is immobile and the microphone may be seen on camera.

For instance, you can use several stand microphones to pick up the sound of a vocal or instrumental group. You may also use a stand microphone for the master of ceremonies (MC).

The placement of stand microphones is determined by sound quality, rather than by picture factors. However, stand microphones should be placed so that they do not impede camera movement or picture quality.

Hanging

Hanging microphones are often used when a boom microphone is impractical because of lack of space or when a large set will not permit rapid boom movement. It is simply a microphone hung from the ceiling or overhead by its cable, placing it out of normal camera range.

The sound source should be fairly stationary when you use a single hanging microphone. You can use a hanging microphone for panel discussions and other types of productions where the talent remains immobile at the time of sound pickup. Several microphones located about the set can accommodate moving talents, but the talents must position themselves near the microphone before speaking.

Most hanging microphones do not produce good audio. If placed too close to walls or overheads, an echo or distorted audio is likely to occur.

Hidden

The sound quality of hidden microphones is mediocre at best, and frequently the object they are hidden in or behind distorts the sound. For this reason, you should use hidden microphones sparingly.

One type of hidden microphone is called a **contact microphone**, because it is in direct contact with the object producing the desired sound effect. An example is a microphone attached to a quick-acting watertight door to pick up the sound of the handwheel and dogs.

TELEVISION LIGHTING

LEARNING OBJECTIVE: *Identify the principles of television lighting.*

Earlier in this chapter, we noted that the television camera changes various levels of light reflected from objects in the scene into electrical impulses of varying strength. Therefore, the primary objective in any television lighting setup is to ensure sufficient illumination for the correct operation of the television camera. However, at the same time, television lighting must support or even establish the atmosphere of the set or scene.

Television lighting essentially follows the same principles as photographic lighting (chapter 11). For the sake of clarity, however, we will take a brief look at lighting as it applies to this medium.

COLOR TEMPERATURE

Before we cover the principles of television lighting, we must address color temperature briefly.

Color temperature is the amount of certain colors that make up a particular white light measured in degrees Kelvin (K). Since the television camera changes images into electronic impulses, the wavelengths of light that vibrate at various frequencies and make up the different hues or colors will have an effect on the output of the camera.

The simplest way to think of color temperature, without getting into complicated formulas, is to say that light of a lower color temperature appears more toward the orange end of the scale, while light of a higher color temperature appears more toward the blue end of the scale.

Studio lighting is standardized at 3200°K. Daylight sources are balanced in the range of 5000°K to 7000°K. You do not have to know what a degree Kelvin is specifically, as long as you accept it as a unit of measure and know how color temperature affects the color television picture.

STUDIO LIGHTING

In this section, we cover the following factors that contribute to proper studio lighting:

- Three-point lighting (key light, fill light and backlight)
- Use of the f/stop

- Proper lighting intensity
- Proper lighting placement
- Skin tones

Key Light

The key light (fig. 14-26) serves as the main light source. It provides sufficient light to operate the camera and acts as the reference point for all other lighting. Place the key light in front of the subject and off to the side at about a 45-degree angle, then elevate it 30 to 35 degrees. You may eventually make adjustment for any number of reasons, but this is a good place to start.

Fill Light

The fill light (fig. 14-27) fills in and softens the harsh shadows created by the key light. Position it on the opposite side of the camera from the key light and elevate it 30 to 35 degrees.

Figure 14-26.—Key light.

Figure 14-27.—Fill light.

Backlight

The backlight (fig. 14-28) is used to separate the subject from the background by casting a rim of light across the head and shoulders of the subject. You should place the backlight at an elevated angle, but be careful not to light the top of the subject's head. A good starting point for the backlight is directly behind the subject, elevated 30 to 35 degrees. If your light is mounted on a stand, move it off to the side a little to get the stand out of the picture.

Use of the f/Stop

Like any other camera lens, a television camera lens produces optimum results when stopped down one or two stops from its maximum aperture. Depth of field also is increased by stopping down. Therefore, your lighting should have sufficient intensity so you can stop down for the best picture possible.

Proper Lighting Intensity

Lighting in television is as important as lighting in basic photography. It has both artistic and technical aspects. Well-planned and executed lighting produces a clear picture with outstanding contrast and depth.

Figure 14-28.—Backlight.

Most television cameras are capable of operating in very low-light levels. However, shooting in dim light may give you video noise and be of generally poor quality.

Proper Lighting Placement

When you set up lighting for a live television production, remember that these productions are continuous; therefore, you must make sure that the lighting you use will be effective from every angle the camera sees in the program. You do not have the luxury of stopping to readjust lighting for each shot. You must make sure that the lighting fixtures and cables do not interfere with the free movement of the cameras. As always, you must plan ahead to avoid embarrassing pitfalls, and then let your television monitor be your guide when making additions to, and subtractions from, your lighting setup.

Skin Tones

Because skin tones are the only “true” means by which a viewer can adjust the color balance of his television set, it is obvious that skin tones must be reproduced accurately and naturally. Proper lighting is the chief way of accomplishing this task.

One way of reproducing natural skin tones is to light the set evenly. If a talent moves from a light scene to a dark scene, the talent’s face should be kept as evenly lighted as possible. The difference between the dark scene and the light scene should be accomplished through backlighting and not the lighting on the talent.

Since extreme shadows take on their own color, you should avoid casting them on the face of the talent. However, do not eliminate facial shadows altogether. Lighten them with fill light instead. A certain amount of shadows are necessary to give character and dimension to the face.

Do not permit color reflections from clothing or scenery to fall on the talent’s face. Likewise, avoid the use of colored lights to light the talent (except for special effects). Save the colored lights for lighting the background.

ENG LIGHTING

When you leave the confines of the television news room or production studio for an ENG assignment, your main concern will be the availability of lights. If you are outdoors on a sunny day, there is not much of a problem. But when you move indoors or shoot at night,

you will need a portable, lightweight and versatile lighting system that either runs on batteries or plugs into a wall outlet without blowing fuses.

Before we cover the components of ENG lighting, keep in mind that the television lighting principles previously covered also apply to ENG lighting.

Portable Lighting Kit

Portable lighting kits will supply you with the lighting equipment you need in most situations. They normally include the following pieces of equipment:

- Lighting instruments
- Tripods
- Short power cables
- Battery packs for each light
- Accessories

Additionally, you may want to include a set of insulated gloves, heavy-duty masking tape or gaffer’s tape and at least one extra bulb for each lighting instrument.

There are many commercially available selections of ENG lighting kits. They usually provide at least enough instruments and accessories for your basic lighting needs.

The color temperature of ENG lighting kit instruments is 3200°K. They are usually variable-focus lighting instruments that may be adjusted for use as a key, fill or backlight.

Accessories

Your light kit should contain accessories, such as barn doors, screens and scrims (fig. 14-29). They are covered in the following text.

BARN DOORS.—Barn doors are metal flaps attached to a ring that is connected to the body of the lighting instrument. They come in either two- or four-door versions. Depending on the type of barn door, you can open or close the doors at the top, bottom or sides to crop the light.

SCREENS.—Screens are small, round or square pieces of metal screening, placed in front of the light to reduce its intensity. They do not change the color temperature of the light. Use screens to reduce or eliminate strong shadows.

SCRIMS.—Scrims are made of clear spun glass or gauze used to diffuse and soften a light. They

decrease the intensity of a light without affecting its color temperature.

THE TELEVISION SET

LEARNING OBJECTIVE: *Recognize the components of a basic television news set.*

All television sets must be designed for the television camera. Everything about the set — size, color, location and props — must be adapted specifically to what the camera sees. A set can be as simple as hung drapes or as complex as a full-scale replica of a ship. However, its actual form must fulfill the artistic aim of orienting the viewers to a place, time or mood.

Just how elaborate your set will be is determined by a number of things, such as the space and materials available, and the manpower you have to design and construct the set.

There are many books on the subject of set design and construction. However, in this chapter we are limiting ourselves to simple set designs that are suitable for use aboard ships and small NMC detachments.

Ideally, you should build an all purpose set — one that is easy to handle and adaptable to a variety of production uses. One set you should consider consists of three 3- by 6- or 4- by 8-foot plywood panels, each 1/4 inch thick. Around the back edges are nailed or screwed 2- by 2-inch furring strips (structural supports) to give it stability (fig. 14-30).

Figure 14-29.—Barn doors, screen and scrim.

Figure 14-30.—Basic television set.

The panels should be hinged together with a type of hardware that allows them to be separated from each other. Paint the panels flat light blue or green, which will make the skin tones look more natural on color television. To reduce glare and reflections from studio lights, you should use flat latex paint.

Before painting the panels, you should check your color choices. Paint small squares of wood and compare them on camera. There must be a distinct difference between set tone and skin tone in order to provide adequate contrast without being excessive. Make sure you select a color that provides suitable contrast when used with either dark or light skin.

SET ERECTION

When you erect a set, you should consider the following three production areas:

- Camera and microphone boom movement. The camera support and microphone boom must be allowed space on the set in which to move. This is especially important for camera angle or position changes and for recording quality sound.
- Talent movement. The talent must have free access if he moves around the set.
- Lighting. The set must provide sufficient lighting for the camera(s).

CREATING THE ENVIRONMENT

A set is used to create the environment or mood of the scene and must be appropriate to the purpose of the program. Sets are generally divided into the following three categories:

- Natural
- Realism
- Fantasy

Natural

A natural set does not represent any specific locale or period and could be, for example, a plain gray background. This type of set can be used for a training program, because there are no background distractions.

Realism

Realism can be achieved in three ways. An exact copy of a period or original scene would be a *replica*, while a setting portraying a type of scene, such as an early sailing ship, is *atmospheric*. The suggestion of an office by the use of a desk and chair, or the shadow of a branch to suggest a tree, is *symbolic*.

Fantasy

The use of abstract shapes or textures can create character and mood. Unrealistic settings have no direct relationship to the real world, but suggest to the viewer a feeling or sense of the location or time.

TELEVISION SHOOTING TECHNIQUES

LEARNING OBJECTIVE: *Identify the basic television shooting techniques.*

Television pictures are subject to the aesthetic rules covered in chapter 12. In fact, because of the wide usage of television, it can even be considered the standard by which we judge most picture composition. However, the following factors unique to television influence picture composition to a certain extent:

- **Small television picture size.** Because of the relatively small size of the television screen, objects must be shown relatively large.
- **Inflexible aspect ratio.** The 3:4 aspect ratio of the picture cannot be changed and all picture elements must be composed to fit it.
- **What the camera sees is what the viewer gets.** The television camera serves as the viewer's eyes; therefore, camera movement, as well as the static arrangement of elements within the frame, must be considered.
- **Time constraints.** Because of the time limitations placed on all television productions, you may not be able to predetermine composition, especially during a live show. Sometimes, all you can do is correct certain compositional errors.

In the television business, the picture on the screen is referred to as a *shot*. A shot may change when either the camera or talent moves. Shots can last for only a few seconds or be as long as a minute or two. In extreme cases, one shot can last the entire program.

As a television camera operator, you must think in terms of shots and master the basic shots of television production.

SHOT CLASSIFICATION

Shots for television (fig. 14-31) are classified in the following manner:

- Extreme long shot (ELS)
- Long shot (LS)
- Medium long shot (MLS)
- Medium close-up (MCU)
- Close-up (CU)
- Extreme close-up (ECU)

Using these terms is the most convenient way for the director to call for the type of shot he wants the camera operator to shoot.

By examining the purposes of the long shot and close-up, you can get an idea of the functions of the other shots. The long shot is used to show as much of the subject as possible while still keeping it recognizable. It is used primarily to show the audience the overall appearance of the whole subject and the subject's relationship to each of the scene elements. This is important, because in subsequent shots (except the extreme long shot), only a relatively small part of the scene will be presented to the viewers. In television work, a long shot is used to orientate the viewers or establish the scene.

The close-up is probably the best television shot. It is one of the most efficient compensations for the small size of the television screen and it is essential to

creating intimacy and getting the viewer "into" the picture. Close-ups are, and should be, one of the most widely used shots for television. The director calls for a close-up for many purposes, the most common of which is to direct the viewer's attention to a specific object or facial expression.

The extreme long shot and extreme close-up are used to describe shots that include an even greater area or a more limited area, respectively. For example, in figure 14-31, the extreme long shot shows the main subject of the scene as a very small mass surrounded by a vast expanse of background and foreground. Consequently, the extreme close-up shows only the cowboy's finger pulling the trigger to discharge his weapon.

FRAMING

In the following coverage of framing for television, we will not dwell on photographic composition, because it was addressed in chapter 12. Instead, we will show you simple line drawing examples of television framing to show you how to present elements within the small 3:4 fixed aspect ratio of the television picture.

Use the following guidelines when you frame subjects or objects:

- **One-talent framing.** When only one talent is talking directly into the camera, place the talent in the middle of the picture to give him maximum emphasis (fig. 14-32).
- **Single-object framing.** When you shoot a single-object, frame it directly in the middle of the picture (fig. 14-33).

Figure 14-31.—Television shot classification.

Figure 14-32.—One-talent framing.

Figure 14-33.—Single-object framing.

- **Framing talent looking left or right.** When the talent looks left or right, give him space within the picture to look (fig. 14-34).
- **Framing talent (extreme close-up).** When you want an extreme close-up of the talent, crop space at the top of his head, not the bottom (fig. 14-35).

Figure 14-34.—Framing talent looking left or right.

Figure 14-35.—Framing talent (extreme close-up).

- **Framing talents of different heights.** When you frame talents of different heights, do not cut the head off one or the other (fig. 14-36).
- **Framing a moving talent.** When you frame a moving talent, give him room in which to move (fig. 14-37).
- **Framing multiple talents.** When you frame multiple talents, such as a “two-shot,” position the camera as shown in figure 14-38. This helps to establish a relationship between the talents.
- **Framing multiple talents with two cameras.** When you frame multiple talents using two cameras, keep the cameras on the same side of the “action axis” shown in figure 14-39. This will prevent the reversal of screen direction in the picture.

Use high and low camera angles with caution. High angles tend to foreshorten legs, while low angles may distort the body and face. Additionally, be aware of set areas or props that seem to be growing out of, or balanced on, a talent's head (fig. 14-40).

Figure 14-36.—Framing talents of different heights.

Figure 14-37.—Framing a moving talent.

Figure 14-38.—Framing multiple talents.

Figure 14-39.—Framing multiple talents with two cameras.

Figure 14-40.—Improperly placed prop and set area.

AREA OF TALENT INCLUDED

The majority of your television pictures will be of people. Accordingly, it is convenient to identify people shots in terms of the portion of the body to be included in the frame.

To help you recognize image size and to frame your talent effectively, you should use the cutoff line system (fig. 14-41). Cutoff lines are natural dividing lines that will help you produce aesthetically pleasing shots.

Use the cutoff lines in the same manner as the six shot classifications previously covered.

NUMBER OF TALENTS INCLUDED

The shot designations that are easiest for you to remember are the ones that refer to the number of people to be included in the picture. When you shoot only one talent, it is termed a **one-shot**, two talents is a **two-shot**, three is a **three-shot** and so forth. However, when five or six people are pictured, it is referred to as a **wide** or **long shot**.

MOVEMENT

Good television needs movement — movement in front of the camera, movement of the camera itself and movement of the picture itself (one picture replacing another).

Figure 14-41.—Cutoff lines.

The movements necessary for good television are divided into the following three categories:

- Primary movements
- Secondary movements
- Tertiary movements

Primary Movement

Movement in front of the camera, usually by the talent, is referred to as primary movement. Primary movement toward or away from the camera is stronger than lateral movement, thus creating more emphasis. Exits and entrances are more impressive when they occur toward or away from the camera.

Remember: you should always lead the lateral movement of the talent with your camera. The viewer

wants to know where the subject is going, not where he has been.

Secondary Movements

Secondary movements (fig. 14-42) may be used to follow primary movements or to change or adjust picture composition. You also may use them to emphasize or dramatize a certain portion of a production.

The secondary movements you will become familiar with are as follows:

- Pan
- Tilt
- Dolly
- Zoom
- Truck
- Pedestal

PAN.—A pan is simply the horizontal movement of the camera on a stationary pedestal used to follow primary action. When panning, you should try to avoid “dead space” between subjects. Do this by positioning the talents diagonally instead of laterally, as shown in figure 14-43. From the point of view of the camera, diagonal staging brings the talents closer together.

When the director wants a pan, he will call for **pan left** or **pan right**.

TILT.—Tilting is simply pointing the camera up or down. The reasons for tilting the camera are similar to those for panning the camera. For example, the height of an object can be shown by gradually tilting up on it, or you could tilt down on something to build suspense.

Figure 14-42.—Secondary movements.

Figure 14-43—Lateral vs. diagonal staging of talent.

The director usually indicates to the camera operator the tilt he wants by ordering **tilt up** or **tilt down**.

DOLLY.—Dollying is moving the camera toward or away from the subject. You can dolly in to increase gradually the size of an object on the screen, or dolly out to produce an opposite effect. Likewise, dollying decreases or increases the field of view.

The director’s orders for dolly are **dolly in** or **dolly out**.

Zoom.—A zoom is made with a zoom lens. It looks like a dolly and is used for the same purpose. During a zoom the camera does not move; therefore, perspective does not change as it does during a dolly.

The director orders **zoom in** or **zoom out**.

TRUCK.—Trucking is the lateral movement of the camera. It is used to follow lateral subject movement or to truck the camera parallel to stationary objects. In either case, camera-to-subject distance does not change.

Truck left or **truck right** are the director’s orders to the camera operator.

PEDESTAL.—When the director calls for a pedestal, the entire camera is either raised or lowered on the pedestal. Pedestalling can provide the audience with a high or low perspective of the subject. The pedestal also can be used to compensate for tall or short camera operators or talents.

Pedestal up or **pedestal down** are the director’s commands.

Keep in mind that secondary movements must have a valid purpose. Do not make them arbitrarily.

Tertiary Movement

Tertiary movement results from a sequence of shots from two or more cameras. When two or more cameras are used, the director can select from a variety of pictures to determine what picture will be telecast and at what time. When more than one camera is used, the director can easily emphasize, deemphasize or show action and reaction in rapid or slow succession.

VIDEOTAPE EDITING

LEARNING OBJECTIVE: *Recognize the fundamental procedures of editing videotape.*

When videotape technology was in its infancy, there was only one way to eliminate unwanted shots — physically cut the tape and splice it back together. This method produced edits that were crude at best, because videotape recording is strictly an electronic process.

Today, the complicated process of cutting and splicing videotape is all but a forgotten art. Now you can edit videotape quickly and cleanly through the use of videotape editing systems or computer software programs.

VIDEOTAPE FORMATS

Before we examine the actual videotape editing process, it is important for you to understand that videotape comes in several different formats. Currently, there are a number of videotape formats used in the broadcast industry, including 3/4 inch super beta, 1/2-inch VHS, 1/2-inch Beta and 8mm, also called Hi8 (fig. 14-44).

There are different schools of thought as to which formats are broadcast quality and which are not, but it is universally accepted that the 3/4-inch super Beta and 1/2-inch Beta are industry standard. These formats are the ones most commonly used at NMC detachments.

Keep in mind that VHS tapes cannot be played on Beta videotape machines, and vice versa (even though they both contain 1/2-inch videotape). Likewise, 3/4-inch super Beta tapes can only be played on 3/4-inch Beta machines and Hi8 tapes are compatible only with Hi8 tape decks.

VIDEOTAPE TRACKS

The electronic information found on a videotape is on the following four tracks:

- Video
- Audio
- Control
- Time code address

Video Track

The video track takes up about three-quarters of the space on a videotape. It is recorded as a series of diagonal lines by one or two rapidly spinning tape heads on the head drum of the VCR.

Audio Track

Virtually all formats of videotape provide at least two distinct areas for the recording of audio information. They are placed in different locations on

Figure 14-44.—Videotape formats.

the videotape but perform the same as regular audio tape.

Control Track

The control track consists of electronic blips or spikes, called sync pulses, recorded in precise intervals of one-thirtieth of a second. Since it provides the necessary foundation for the editing process, **you cannot edit without a control track on your blank (source) tape in the insert edit mode.** The insert edit mode is explained later.

Laying the control track on a blank videotape is the first step in the videotape editing process in the insert edit mode. Most television studios have a “black burst” generator that produces a crystal black signal you may record and use as a control track. You also can record a control track from another tape — for example, a tape that has color bars and tone.

Time Code Address Track

The time code address track is used to record cuing information for editing. This information may consist of audio or visual time/frame identification.

Figure 14-45 shows the location of all four tracks on a 3/4-inch super Beta videotape.

VIDEOTAPE EDITING PROCESS

Videotape editing is essentially a transfer process in which a playback VCR, containing the recorded segments, transfers its material onto an edit/record VCR that assembles the various segments into a finished form. The editing control unit (ECU) is equipped with highly sophisticated electronic circuitry and allows the operator to control exactly where the old material on the edit/record VCR will end and the new material playing in from the playback VCR will begin.

The precision of the edits depends largely on your reaction time and skill. You must precue both videocassette tapes accurately before the editing begins, since you will control exactly where and when the edit will occur while the two VCRs are rolling.

You will do your editing in what is called an editing cell. Most NMC detachments have one or more editing cells containing the following equipment:

- Playback VCR
- Edit/record VCR
- Television monitor for the playback VCR
- Television monitor for the edit/record VCR
- Audio mixer
- ECU
- Character generator
- A typical editing cell is shown in figure 14-46.

EDITING MODES

On an editing cell, you may make either assemble edits or insert edits. Both are explained in the following text.

Assemble Edits

In the assemble editing mode, the ECU adds control track and program footage (both audio tracks and the video track) to the edit/record VCR at a predetermined in-edit point. The edit/record VCR continues recording the new information and the control track until it is stopped. When you are assemble editing, you are inserting a new control track at each in-edit point and ending a control track at each out edit point. Your video may be unstable (picture tearing or breakup) at the edit points during playback. Therefore, you should allow for extra video after your intended stop/out-edit point — otherwise, you will not

Figure 14-45.—Track location on a 3/4-inch super Beta videotape.

Figure 14-46.—Videotape editing cell.

be able to edit onto the last part of the video. Assemble edits are very convenient because you simply add segments to build the video story or program.

Insert Edits

Insert editing allows you to add or change video or audio separately or together without affecting the control track. As you insert the new material over the existing information, you use the control track already established on the edit/record videocassette to lock the signal into synchronization.

The main drawback of insert editing is that you must lay a long enough control track on the tape before you start editing. A one-hour program tape requires you to lay one hour of black or color bars and tone before you start the editing process.

NOTE: After laying the control track in the assemble mode, be sure to switch to the insert mode on the ECU. If you remain in the assemble mode when you make your first video or audio edit, the end of the edit will look like a green flicker on the television monitor. This is caused by a break in the control track.

There is no way to correct this break without relaying the control track for the entire length of the tape. The best approach for you to take is to stay in either the assemble or insert mode.

EDITING TECHNIQUES

The two basic editing techniques in videotape editing are **continuity cutting** and **compilation cutting**. Both are explained in the following text.

Continuity Cutting

Continuity cutting is the most commonly used method of editing videotape for news or feature releases. It is used when the storytelling is dependent on matching consecutive scenes. Continuity cutting consists of matched cuts in which continuous action flows from one shot to another.

The three transitional devices associated with continuity cutting are the **cutaway**, **cut-in** and **crosscutting**.

CUTAWAY.—When the action shown is not a portion of the previous scene, a transitional device, known as a cutaway, is used to change positions, movements or characters or to denote a lapse of time. This eliminates a mismatch, or jump cut, that would cause the segment to appear jerky or out of sequence. Cutaways are often termed *protection, reaction, insert* or *cover shots* and are thought of as secondary action shots.

For example, if the main thought is centered around a parade, cutaways might consist of closeup shots of the crowd. Children may be shown watching intently, eating candy or applauding; adults may be wearing different expressions of emotion or carrying children on their shoulders (fig. 14-47). These shots are of human interest and are related to the main story, but are not actually a primary part of it.

If you have a good selection of cutaways, often you can make a marvelous story out of an otherwise drab and commonplace event. The cutaway can cover a multitude of camera operator errors and result in the formulation of an exciting segment.

Cutaways should last between three and five seconds.

CUT-IN.—Another method used to denote a lapse of time is the cut-in. Unlike the cutaway, the cut-in is a part of the primary action, rather than the secondary action. For instance, to denote a person climbing a long flight of stairs, you establish the individual at the start of the climb, then cut to a close-up of feet as they take the steps. After you establish the shot (three to five seconds), you cut back to the person at the top of the stairs (fig. 14-48). A person can appear to walk a city block in just a few seconds by showing feet walking or a hand carrying a briefcase.

CROSSCUTTING.—Crosscutting is the old standby of videotape editing. In crosscutting, you use shots from two different actions or events that will finally be related. A time-honored example is the “meanwhile, back at the ranch” style, or the hero riding hard to save the life of the heroine who has been chained to a buzz saw by the villain (fig. 14-49). The action would be cut back and forth between the desperate rider and the saw as it comes dangerously close to the heroine’s head, showing the progress of each, then finally relating them as the rider arrives at the last moment to save the heroine.

Figure 14-47.—Cutaway.

Figure 14-48.—Cut-in.

Figure 14-49.—Crosscutting.

Compilation Cutting

The second method of videotape editing is compilation cutting. This is used in documentary-style stories of surveys, reports, history or travelogues. Segments are tied together through narration. The narrative explains the shots, which may have little or no matching relation. These shots or scenes may be long or short shots, or they may go from long shots to close-ups without any special transitions.

BASIC EDITING PROCEDURES

Before we cover the basic procedures of editing videotape, keep in mind that the editing procedures and techniques in place at your NMC detachment may differ from what is portrayed in this section. For training purposes, let's assume a script has been written and the primary narration has been recorded on the production tape. (This is a normal news/production requirement.) A typical editing sequence might look like this:

1. The editor will work from a log that lists all of the scenes on the tape(s). It may be prepared at the time of the shooting or as the tape is being reviewed at the station or your office. The log will briefly describe the scene and indicate where it is located on the tape (using the counter on the playback VCR).
2. The producer, editor and sometimes the reporter will decide which scenes to use, the order in which to show the scenes and the amount of time you have to tell the story. In some instances (especially at small NMC detachments and aboard ships), one person will make all of these decisions.
3. The editor prepares a blank videocassette with countdown leader and enough control track to cover the length of the story. He then loads it into the edit/record VCR.
4. The raw video is loaded into the playback VCR. Now the editing process is ready to begin.

5. The story is assembled and edited according to the predetermined sequence. Sometimes the audio track is recorded first and the visuals added later. At other times, the sequences are assembled in order, depending on the type of story and available footage.

6. The editor labels the smooth tape with the title of the story, date and run time. A supervisor will review the story and make corrections (if necessary) before it airs.

The technical side of the editing process is fairly easy to learn. With today's technology, the procedure is almost foolproof. Some editing systems use computer software programs that allow you to use Time Code editing to set all of your edit in and out points ahead of time, including special effects, graphics and audio and video mixes and dissolves. The capabilities of your editing system will control the number of special effects you will be able to use with your television production. The latest software programs available allow you to produce professional looking, broadcast quality video, with minimal manpower. Nevertheless, a good videotape editor must have a thorough knowledge of many related skills to provide viewers with a simple, yet effective, message.

VIDEOTAPE SCRIPTING

LEARNING OBJECTIVE: *Identify the format of a script that accompanies a video news release.*

When you write a script to go with a video news release, make sure your pictures tell the story. The narration should supplement them, not overpower them.

A video release (fig. 14-50) is similar in appearance to the radio news releases shown in chapter 13 (administrative information, four-unit heading, release line, etc.), except you use two columns for the actual script. The left column is devoted completely to

PAGE 1 OF 1

RELEASE NO. 17-01

ARMED FORCES DAY

May 15, 2001

60 SECONDS

FOR IMMEDIATE RELEASE

VIDEO

AUDIO

NEWSCASTER:

NEWSCASTER:

Armed Forces Day was celebrated today at Naval Air Station Samara, and the red carpet was rolled out for seven thousand visitors.

SAILORS MARCHING

(ON CUE) Many guests arrived early (NAT SOUND) enough to see a contingent of sailors parade on Burnitz Field. They are recent graduates of Computer Repairman "A" School and will soon report to their assignments with ships of the fleet. Many spectators at today's parade have sons or daughters marching in the ranks.

ADMIRAL ON STAND

(ON CUE) Rear Admiral Davey Jones, (NAT SOUND) the Vice Chief of Naval Education and Training, inspected the graduates as they paraded by the reviewing stand.

EXHIBITS

(ON CUE) Visitors also saw special (NAT SOUND) exhibits showing the missions of the tenant commands at the air station. A panel of judges, made up of Samara residents, chose the most outstanding exhibit.

MAYOR

(ON CUE) Mayor Jack Crevalle awarded (NAT SOUND) the top prize to Petty Officer First Class Kenneth Aidem, representing the air station's Crash and Salvage Division.

###

Figure 14-50.—Video news release.

the video, or visual section, and the right column to the audio, or sound section, of the release.

Note that all of the information in the video column is in capital letters. This tells the news director that the information is there for information purposes only and is not to be read by the talent.

Below each video entry (except the first), in parentheses, is the phrase NAT SOUND. This tells the newscaster he will speak over the natural sound recorded when the scene was shot. If there was no natural sound present, you will use "SIL" for silent.

At the beginning of paragraphs two through four in the audio column are the words *ON CUE*. This instructs the newscaster to look at the television monitor in the studio and wait for the scene described in the video column to appear before continuing.

In a standard video news release, lines average five words in length and are read at an average pace of 28 to 32 lines per minute.

TELEVISION PROGRAM MATERIALS

LEARNING OBJECTIVE: *Identify the television program materials available from AFRTS-BC and the Navy Motion-Picture Service (NMPS).*

AFRTS-BC provides television news, information and entertainment programming for the exclusive use of AFRTS outlets, including all NBS detachments. It is the only source authorized to negotiate, procure and distribute commercial and public broadcast programming.

AFRTS-BC acquires its programming at a minimal rate because of a special agreement with distributors, performers' unions, guilds, music licensing organizations and industry regulatory agencies. Therefore, special handling procedures and use restrictions are required to ensure security of the videocassettes and prevent copyright violations. These regulations and restrictions protect the rights of the commercial broadcasting industry as guaranteed by the U.S. Civil Code.

This section is intended to acquaint you with the different program materials offered by AFRTS-BC. For more detailed information, consult *American Forces Radio and Television Service (AFRTS) Program Materials, DoD Directive 5120.20-R, Appendix F*.

TYPES OF AFRTS TELEVISION SHIPMENTS

AFRTS currently circulates programs to outlets on videocassettes. Program packages are broken down into the following categories:

- Television weekly (TW)
- Television weekly "B" (TWB)
- Television weekly "C" (TWC)
- Television priority "A" (TPA)
- Television priority "B" (TPB)
- Television library (TL)
- Television temporary library (TTL)
- Television material (TM)
- Television weekly (TW)

The Television Weekly (TW) is the largest package of television programs (approximately 80 hours) supplied to deployed ships and some remote NMC outlets that do not have satellite capabilities. This package features U.S. broadcast and cable network programs, preteen and preschool programs, talk shows, soap operas, quiz shows, movies, mini-series, information, religious and filler programming. For deployed units, one package is in use while two others are either at the outlet waiting to be used or en route. The TW package is circuited, meaning it is passed from one station to another along a predetermined "circuit" of several stations.

Television Weekly "B" (TWB)

The Television Weekly "B" (TWB) is essentially the same as the TW package but does not contain the preteen and preschool programming. It is circuited to Super-SITE and SITE ships and contains approximately 72 hours of programming.

Television Weekly "C" (TWC)

The Television Weekly "C" (TWC) is a scaled-down version of the TWB (roughly 42 hours of programming) and is circuited to smaller ships and submarines.

Television Priority "A" (TPA)

The Television Priority "A" (TPA) contains about 12 hours of timely programming. It is not circuited but

is sent directly to authorized outlets (primarily Navy ships) for use at the earliest possible date. If your detachment has access to SATNET (the worldwide AFRTS 24-hour satellite network), you will not receive the TPA package.

Television Priority “B” (TPB)

The Television Priority “B” (TPB), while not currently in use, is reserved for possible future application.

Television Library (TL)

The Television Library (TL) contains accountable library videocassettes shipped periodically to full-service, land-based outlets and fleet circuit managers for permanent retention. It is used to supplement normal programming or to fill emergency requirements.

Television Temporary Library (TTL)

The Television Temporary Library (TTL) consists of accountable library videocassettes provided to meet special short-term requirements, such as holidays and anniversaries, or when AFRTS-BC requires that the materials be returned within one year. Return dates and instructions appearing on TTL packing lists must be strictly followed.

Television Material (TM)

The Television Material (TM) contains nonaccountable library materials provided for single or repeated use and subsequent local disposal. Other usage conditions may exist and will be explained on the packing list.

CUING AFRTS VIDEOCASSETTES

Most AFRTS videocassettes that are longer than 15 minutes contain AFRTS system cues at the end of the programs. The system cue is contained on a five-second segment that identifies AFRTS as the program source. It also alerts the control board operator that he must make a transition in five seconds.

Videocassettes 15 minutes in length or less do not contain system cues but are cue-dotted by AFRTS-BC. Cue-dotting is accomplished by inserting the proper series of cues electronically during videocassette editing. The “dots” are actually small white squares that appear in the upper right-hand corner of the

television screen. Multiple videocassette programs are cue-dotted at 10, seven and two seconds from the end of each tape, except the last tape of the program. This tape will contain an AFRTS system cue instead of the cue dots.

EDITING AFRTS TELEVISION MATERIALS

AFRTS television program materials are intended to be used as received. Outlets may not duplicate, edit or delete any part except in the following circumstances:

- To remove host-country sensitivities. (This must be done on a duplicate (dub) tape and not the original AFRTS-BC videocassette.)
- To air short excerpts for the promotion of upcoming programs (not to exceed two minutes).
- To remove commercials or commercial slugs, such as “Place Commercial Here” and “Splice Here.” If this happens, board-fade the unwanted section and cover it with an AFRTS or locally-produced spot.

NOTE: Do not confuse commercials with sponsor or product mentions or identification, visual or aural, that are integrated into openings and closings in a way that makes their retention necessary for program continuity.

- To shorten the length of videocassettes specially designated by AFRTS-BC for future use.
- To repair damaged videocassettes.

Make sure you consult *American Forces Radio and Television Service (AFRTS) Program Materials, DoD Directive 5120.20-R, Appendix F*, for further details.

HANDLING AFRTS VIDEOCASSETTES

Cleanliness is paramount when you handle AFRTS or any other types of videocassettes. Areas where television materials are stored or handled should be clean at all times and, if possible, ventilated with filtered air so that dust is blown out, rather than drawn in. AFRTS recommends that smoking, eating and drinking be prohibited in these areas.

Videocassettes must be kept in their shipping containers in a secure, atmospherically controlled environment until they are ready for use and then returned immediately after use. This keeps the tapes clean and virtually eliminates the possibility of mixing programs with other videocassette shipments.

In general, the recommended storage conditions for videocassettes are a relative humidity of 50 to 60 percent and a temperature of between 60 and 80 degrees.

Do not leave videocassette containers open! An open container is an invitation to dust and debris. If you have a dirty container, remove the videocassettes and vacuum the container. When the container is clean, replace the videocassettes in the order specified on the packing list.

NAVY MOTION PICTURE SERVICE

The Navy Motion Picture Service (NMPS) in Brooklyn, N.Y., provides most Navy ships with

first-run movies on Beta videocassettes. The tapes may be aired either at sea or in port. Eligibility for NMPS service is based primarily on deployment duration, tape storage capability and security.

You may retain NMPS videocassettes for three or four years, depending on the lease agreement with the particular movie companies and NMPS. Lease expiration dates are indicated on each videocassette case and its accompanying synopsis card.

For further information about the NMPS Videocassette Program, refer to the *Navy Entertainment Movie Program Administration and Operations Manual*, NAVMILPERCOM 1710.1.

CHAPTER 15

RADIO AND TELEVISION INTERVIEWING

One of the most difficult tasks you will encounter as a Navy Journalist is serving as a radio and television interviewer. In the space of a few minutes, an interviewer must draw out answers and reveal the attitudes of an interviewee that would normally take hours or even days of ordinary conversation. He must do it with various types of people, in front of cameras, under hot lights and in front of microphones.

As a broadcaster serving at an NBS detachment or aboard a SITE-equipped ship, you will conduct a wide variety of radio and television interviews. Your interview subjects may be from within the command—for example, PN1(AW) Boate, the command Sailor of the Year; Lt. Cmdr. Frost, the newly reported chief engineer and former Miami Dolphins special teams player; or SA Doe, the mess cook who rescued a drowning youngster from a public swimming pool. Conversely, you may be asked to interview music and motion picture stars, politicians, community leaders and coaches of youth sports teams.

Regardless of the importance or prominence of the subject, you must not forget to take the following three actions to make every radio and television interview a success:

- Extract the facts
- Emphasize the important details
- Keep the audience informed

TYPES OF INTERVIEWS

LEARNING OBJECTIVE: *Identify the most common types of radio and television interviews.*

With few exceptions, interviews for radio and television are generally in one of the following three categories that are covered in the succeeding text:

- Opinion
- Information
- Personality

OPINION INTERVIEWS

While personal opinions may surface in other forms of interviewing, the thoughts or opinions (whether right or wrong) of the interviewee are in the spotlight in this type of interview.

The opinion interview is usually applied in broadcasting to support expanded news formats. A common form of this type of interview is the “man on the street” interview. The broadcaster stations himself in a busy public area and stops individuals to ask a question on a specific issue. Your station manager might send you out to ask for opinions or comments on a radical new fashion or fad, the completion of a commissary or base exchange, the outcome of a sporting event or countless other situations. (See figure 15-1.)

Commercial stations usually ask a question dealing with a highly controversial issue. However, policy dictates that NBS detachments and other military broadcast outlets refrain from posing questions that would adversely affect the morale of U.S. personnel or serve to undermine the commander’s authority. Check with your supervisor or the PAO if you plan to do this type of interview.

When you use the opinion interview, avoid the “stacked deck” method of gathering data—that is, do not seek comments from one particular group of people. Gather your responses from young and old,

Figure 15-1.—On the street interview.

male and female and people of various ethnic backgrounds. This will give your completed program credibility.

In addition, do not ask a “loaded” question during an opinion interview. Note the following example:

Example: “Excuse me sir, don’t you think the new commissary is being constructed in an inaccessible location?”

Such a question leads the interviewee toward a particular response. In the preceding example, chances are very good the interviewee will respond with a yes answer. (Formulating interview questions will be covered later in this chapter.)

Before you conduct an opinion interview, prepare your questions in advance and make sure you research the topic thoroughly. The audience does not expect the man on the street to be an expert, but it expects the interviewer to be thoroughly knowledgeable of the subject being discussed.

INFORMATION INTERVIEWS

The information interview is the most common form of interview used at NBS detachments. The civilian broadcast equivalent is the public service interview. Your subject may be the chief master-at-arms discussing local activities during Crime Prevention Week or the MWR director talking about what activities are planned at the recreation center. You might do an interview with a physician for a health series or the CO for your weekly captain’s call.

Whatever the topic may be, your goal during the information interview is to inform the audience. You should research the topic and prepare your questions well in advance. You do not have to show your questions to the interviewee before the program, but it helps if you give your subject an idea of what you will ask. This helps you keep your topic on track during the interview.

As a Navy broadcaster, you may be assigned to cover a wide range of adverse news situations. When you conduct an interview in conjunction with an accident or disaster, be sensitive to the feelings of others. Be careful how you phrase your questions and watch your tone of delivery. Use tact in finding out the five Ws and H and double-check your facts. If you need assistance in gathering the facts, consult your colleagues in the public affairs office.

PERSONALITY INTERVIEWS

Another form of interview often assigned to Navy broadcasters is the personality interview. In this case, the person is important because of what happened to him, what he has done or the position he holds. It may be a timely feature story interview, a regular series or a celebrity interview.

During the personality interview, you must be versatile enough to make your delivery match the event. You must be sensitive to the situation and not antagonize the interviewee by making light of something he takes seriously.

Often, Navy broadcasters will be assigned to interview famous recording artists, motion picture stars or sports celebrities. Be aware that celebrities are accustomed to being interviewed and are well-seasoned at this art. If you are not careful, the celebrity you are interviewing may try to run the show.

Again, the key to producing a good personality interview is research. Read every available newspaper or magazine article on your subject. Know about his past, his rise to success, what he is doing now and his plans for the future. Write intelligent and stimulating questions. Personality subjects appreciate new material and grow weary of answering the same questions time and time again.

INTERVIEW METHODS

LEARNING OBJECTIVE: *Recognize the most common interview methods.*

What method should you use to conduct an interview? The answer depends on the subject, time, place and other intangibles that make each interview different.

In most circumstances, you will use one of the following three interview methods to get the required information for your program:

- Scripted
- Semi-scripted
- Ad-lib

SCRIPTED

In the scripted interview, all the questions and answers are prepared in advance and the interviewee(s) simply read(s) the prepared text.

While certain high-ranking officers and officials involved in sensitive or security areas may prefer this

method, the scripted interview must not sound like it is being read. If it does, then the program becomes stilted and the conversational aspect of the interview is lost. Likewise, listeners or viewers will lose interest and tune out the message you are trying to deliver.

Unless security or policy concerns dictate the use of the scripted interview, you should avoid it.

SEMI-SCRIPTED

The semi-scripted interview method is the best for most interviews. With this interview, the interviewer researches the subject and interviewee, discusses possible questions in advance and perhaps even rehearses the interview. This method provides an excellent balance between the ad-lib (covered next) and the fully scripted method and is personal, yet focused.

AD-LIB

While all interviews should be conversational, the ad-lib method can carry this to the extreme. The unprepared atmosphere of the “just sit down and start talking” method can cause stuttering, repeated questions or answers, off-the-subject discussions, long pauses and security or propriety violations. For these reasons, you must be focused when you use the ad-lib interview method.

Areas where the ad-lib method can be used include occasions of spontaneous news, such as on-the-scene reports and other “live” topics of interest.

INTERVIEW FORMAT

LEARNING OBJECTIVE: *Recognize the areas that comprise the format of an interview.*

Now that you know the different types of interviews and the methods with which to conduct them, we will examine the standard interview format. Simply stated, all interviews have the following three parts:

- The opening
- The body
- The closing

THE OPENING

The opening clearly identifies you, your subject and the topic. This allows your audience to know “up

front” whether the interview has any direct interest to them. Additionally, the opening can give your location to establish a local tie-in or explain any background noises.

THE BODY

The body is the interview itself — the actual questions and answers. At this point, the interview takes shape and becomes a reality.

THE CLOSING

The closing is an abbreviated form of the opening. During the closing, you can summarize briefly the content of the interview and once again identify yourself and your guest.

The opening and closing may be the most important parts of the program, since the opening grabs the audience’s attention and the closing provides a conclusion to the story being told.

After you have determined the focus of the interview and formulated your questions, you may write and record the opening and closing before you talk to your guest (if time permits). If you want ambient (natural) sounds for the opening and closing of a radio interview, take your script along and read it at the interview site. For television, memorize those parts you will do on camera. Of course, if you need additional information that you will gather during the interview, you can record the opening and closing afterward.

Keep in mind that you may deviate from this interview format. Be creative with visuals or audio and vary the wording of the opening and closing so your audience is not barraged with “carbon copy” interviews.

LIVE AND TAPED INTERVIEWS

LEARNING OBJECTIVE: *Identify the types of live and taped radio and television interviews.*

Only under the most extraordinary conditions will you conduct a live television interview; therefore, we will not cover it in this section. However, when you plan a radio interview, you should consider whether you want to present it live or on tape and address the concerns of taped television interviews. Both the live and taped interview methods are covered next.

LIVE INTERVIEWS

Live interviews, especially opinion interviews, are difficult to control from both a propriety and sensitivity aspect. However, there are several ways you can conduct live interviews on radio. They are as follows:

- Studio
- Remote
- Telephone

Studio

The studio interview is usually either a personality or informative interview. Make sure you have enough microphones in the studio for all interview participants. Although a common setting for a live radio interview, the studio interview tends to present a sterile atmosphere. Additionally, a strange location may intimidate the guest, preventing him from really “opening up.”

Remote

The remote interview is either the informative, personality or “man on the street” type of interview and it is often conducted at a specific event. The major disadvantages of a remote interview are the limitations in station equipment and the lack of control over the environment. Nevertheless, this type of interview gives you the advantage of timeliness. (See figure 15-2.)

Telephone

The telephone interview can be either an opinion, an informative or personality interview. Good audio levels are sometimes hard to get during a telephone

interview, so make sure you consult your engineer before airing the interview live. Furthermore, make sure you inform the interviewee of your intentions before you air the discussion live.

TAPED INTERVIEWS

The taped or “canned” interview is the preferred method of presenting a radio or television interview. Although it usually lacks action, presence and spontaneity, the taped interview gives you total control of timing, format and content and it allows you to choose the means or location to bring out the best in your guest and subject.

When you tape an interview from a remote site, make sure the background noise enhances the interview, rather than disrupts it. Your knowledge of the directional capabilities of microphones and selecting the correct one will help you in this area.

You can respond quickly to news events by taping interviews over the telephone. Use only portions of the interview as news inserts or actualities because the audio quality is generally poor and would become distracting over a long period. If your questions are to be used as part of the interview or actuality, make sure the audio levels are balanced.

You may have no choice as to whether you do a television interview in the studio or as a remote. If you do have a choice, the studio is preferred for a self-contained interview program. The studio provides a controlled environment. The sets are ready, shots and camera movements are planned, audio is checked well in advance and the crew is prepared long before the interview begins. As you learned in chapter 14, the set determines the tone of the interview. Viewers form their first impression from the set. It should complement the interview and not compete for the viewers’ attention.

Many of the radio or television interviews you do will not be in a studio. By recording an interview on location, you add excitement, realism and a sense of being there. Often an interview subject is much more comfortable in his own office or surroundings — rather than in a studio — and this usually leads to a better interview.

Before you tape a remote interview (if time permits), survey the location to avoid problems. Your primary consideration should be checking the acoustics and deciding if ambient noise will be distracting. The use of background noise can enhance

Figure 15-2.—Remote interview.

the interview if it is unobtrusive and blended at a level that does not overpower the conversation. Remember that your equipment may record noise you are not aware of from air conditioning or other electronic equipment. Identify an alternate location if you think you will encounter problems.

INTERVIEW PREPARATION

LEARNING OBJECTIVE: *Identify the preparatory considerations of radio and television interviews.*

The preparation considerations for radio and television interviews are similar. Whether you are assigned an interview or tasked to develop the program yourself, thorough planning is essential.
